The Ministry of Health had agreed to a suggestion from the Committee that the status of the hospital member of the Medical Interviewing Committees under the Disabled Persons (Employment) Act should be clarified, and in the latest instructions to regional officers this member was defined as one possessing a higher qualification in medicine or surgery. The Ministry had also made it clear that either the industrial doctor or the hospital member was eligible for chairmanship of the committee. The question of sessional remuneration of specialist members and payment of travelling expenses was under consideration, and any decision subsequently reached would be given retrospective effect. With regard to sessional fees for members of Disablement Advisory Committee panels, the Ministry had offered an increase of from 1½ to 2 guineas, but the General Practice Committee decided to urge again that the minimum fee should be £2 5s. per session, plus mileage payment at standard rate and subsistence payment in accordance with the Civil Service scale.

Entrants to the Mining Industry

The Chairman reported that he with the Assistant Secretary had met the chief medical officer of the National Coal Board on a number of matters. It had been urged that pre-employment medical examinations of entrants to the mining industry should be undertaken by medical boards, but the chief M.O. was not convinced of their advantages, and considered that an individual practitioner with a knowledge of the industry could undertake the work equally satisfactorily. Medical boards would have to serve a wider area, involving travelling and subsistence allowances and affecting the cost of the examination. The coal areas, he said, were not so compact that these factors could be disregarded. The Committee resolved to explore this matter further.

The question of international vaccination certificates for attending passengers to the Far East occupied the Committee for some time. The authorities of Hong Kong and Singapore have insisted on certificates being signed by medical officers in the service of central or local governments and have refused to accept the certificate of a general practitioner as valid; in some other quarters, while the certificate of a general practitioner is accepted, it requires to be countersigned by a Government medical officer. It was stated that the whole question had been reviewed by an expert committee, which is recommending to the World Health Organization at meetings shortly to be held that, although it is advisable that certificates be countersigned, they should not be rejected merely on the ground that this has not been done.

Burden of Certification

The Committee reviewed the draft statement of evidence which it is proposed to submit to the Departmental Committee on Certification. The evidence included a classified list, not exhaustive, of certificates which general practitioners are commonly required to give at the present time. These were set out in four groups, making 32 items in all. A recommendation was passed that the Association was satisfied that effective steps

could be taken to lighten the burden of certification. The steps suggested included reducing the number of varying forms of certificate in order that one or two stereotyped forms might serve a variety of purposes; simplifying the forms of certificate wherever practicable; ensuring that new certificates are not introduced without due consideration and consultation with the profession; abolishing the necessity for giving medical certificates for commodities in short supply where there is no official sanction for such requirement; and reducing the frequency with which certificates may be renewed. The sub-committee which has prepared the evidence rather drastically pruned the occasions for which practitioners may be expected to give certificates, and the General Practice Committee made some further deletions. A model form of certificate was approved.

WORLD MEDICAL ASSOCIATION

The General Assembly of the World Medical Association at its meeting in Paris last September delegated to the Council the task of selecting a site in North America for the headquarters of the Association, the selection being subject to the approval of the American Medical Association and the Canadian Medical Association. The Chairman of the Council, Dr. T. C. Routley, of Canada, and Dr. Louis H. Bauer (U.S.A.), Member of Council, have reported that on behalf of the Council they are acquiring offices in the building of the New York Academy of Medicine at 2, East 103rd Street, New York. It is believed that they will admirably meet the needs of the Association.

The Council will hold a meeting in New York on April 26-9, and it is hoped that the new offices will be available by that time. After the meeting the Members of the Council will be the guests of the American Medical Association, the Mayo Foundation, the University of Minnesota, and some other universities for a ten-day tour which will take them as far west as Minneapolis.

HEARD AT HEADQUARTERS

Public Relations

The appeal is now to Caesar, Caesar being the British public, and the public relations organization of the Association (both the department at Headquarters and the public relations committees and their secretaries in the Divisions) is working hard. A Public Relations Conference assembled within 48 hours of the announcement of the plebiscite, and many of the secretaries brought forward ideas which they have successfully followed in their own localities. Every channel of publicity—leaflets, posters, public meetings large and small, the local and national press—was discussed. One of the difficulties is, of course, that while the individual doctor is regarded with affection doctors collectively do not command the same regard, and never have done. Moreover, the patient who is a most sympathetic and receptive person when seen by himself in the surgery is a very much more sceptical sort of person when he is one of a crowd at a public meeting. Another difficulty is that there is not one public, but two, or many, and that the approach which may be suitable to the readers of picture papers would be despised by those who take their views from the serious journals, and perhaps ten of the latter are more important in the formation of public opinion than a hundred of the former. But the Public Relations Department has got all this in hand.

How Many Patients a Day?

How many patients can a doctor see in a day? There has been an amusing correspondence in the American journals on this subject. A Wisconsin doctor put in a claim that he could see 75 patients a day. He was taken to task by a New York doctor, who pointed out that even if each patient took only ten minutes that would still add up to 12 hours, and even then it would mean that his chair never got cool. "A good service,"

he said, "cannot be given in ten minutes." But then came along a doctor from California who went whizzing past the Wisconsin record and declared that he saw personally as many as 120 patients a day, and his day was less than 12 hours. Easily done, he says it is: it is just a question of having sufficient space and organized team-work between doctor and nurse. It is true that a new patient may even require as much as 15 minutes, but on the other hand it takes only two or three minutes to give a patient a repeat injection and send him on his way. He concludes, perhaps rather ingenuously, "Maybe we don't give the best, but we treat the most."

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar.

Non-County Borough Councils.—Dartford, Radcliffe (limited to future appointments), Tottenham, WallSEND.

Urban District Councils.—Denton, Drydlsden, Houghton-le-Spring, Huyton-with-Roby, Portslade, Redditch (restricted to new appointments), Stanley (Co. Durham), Tyldesley.

Scottish Burghs.—Motherwell and Wishaw.

H.M. Forces Appointments

ROYAL AIR FORCE

DENTAL BRANCH

D. C. P. BAKERSEA to be Squadron-Leader.

ROYAL AUXILIARY AIR FORCE

L. WATT to be Flight-Lieutenant.

ROYAL AIR FORCE VOLUNTEER RESERVE

Flight-Lieutenant D. M. BROWN has resigned his commission, retaining the rank of Squadron-Leader.

Flying Officers T. M. Cullingworth, A. Fernandez, R. L. Goldson, D. B. Harnes, J. M. Kelly, J. McNally, J. E. Marrett, J. W. Moffitt, C. H. Neville-Smith, B. Poole, S. R. Sims, D. R. Smith, L. Temkin, F. G. Tuffnell, C. N. Atkinson, C. B. Burdett-Smith, J. P. Clayton, D. E. Cullington, A. L. T. Eason, J. H. H. Glin, L. W. Godfrey, G. R. S. Grogono, W. J. L. Harries, T. D. Hawkins, J. P. Jackson, A. R. Jones, T. J. Jones, R. E. Leighton, D. L. Mackinnon, W. T. S. Moore, R. A. Morris, R. Owen, R. A. Parker, J. P. Penon, P. R. B. Sankes, W. M. B. Strangeways, W. K. Sutton, S. Beacon, A. J. Beale, A. V. Craig, S. Croft, G. Forrester, K. B. N. Freeman, L. M. Green, W. P. Gurassa, J. D. Hennessy, J. J. Henry, F. G. Ince, F. J. G. Kinsella, H. R. Macleod, R. S. Male, N. G. Nicholson, J. A. O'Garra, B. H. Pentney, T. W. Price, B. E. Roebuck, W. H. R. Smith, S. A. Somers, J. Walsh, R. G. Welch, F. J. Woodley, and J. M. Talbot to be Flight-Lieutenants (Substantive).

The following have been granted the Substantive rank of Flight-Lieutenant: R. H. Sage, W. M. Sandeman, G. E. Schofield, M. G. Scott, P. F. Scott, R. M. E. Seal, G. H. Seal, J. S. T. Searle, P. Selzer, D. S. Sharpe, W. J. W. Sharrard, C. S. Shaw, J. F. Shaw, D. W. S. Sheldon, F. L. Shepherd, A. Sherlock, D. A. Sherman, J. G. Shirreffs, H. Shooman, L. Shuck, R. E. Sidebotham, E. Silver, P. H. S. Silver, L. Silverstone, R. D. Simpson, D. H. Sinclair, J. A. Sindell, I. P. D. W. Skempton, H. H. Slack, H. R. Smart, J. G. Smirk, E. R. Smith, H. H. Smith, C. J. W. Soutar, J. Stevenson, R. H. Stillman, J. B. Stirling, D. F. Street, S. D. K. Stride, H. F. Surden, G. P. Sutherland, H. D. Symon, J. McA. Taggart, C. E. Tait, G. S. Tapsall, J. C. Taylor, J. G. Taylor, T. Taylor, W. C. Taylor, D. C. Tennant, G. J. Tewfik, D. L. C. Thomas, J. M. Thomas, M. Thomas, P. H. Thomas, J. L. G. Thomson, T. J. Thomson, W. S. T. Thomson, M. Tobias, C. Todd, W. F. Toomey, D. K. M. Tove, P. R. Travers, D. E. Truscott, R. R. Trussell, A. J. Underwood-Whitney, F. N. Valdez, J. G. Vause, A. D. Verniquet, C. C. Vidot, P. Vlasto, J. C. L. Wade, H. Wainstead, I. A. Waldie, G. A. Walker, R. V. Walley, J. Ward, N. C. T. Watford, D. A. Watkins, I. G. Waugh, J. A. Waycott, M. T. Welford, G. G. Wells, P. W. Wells, P. West, G. A. Wetherell, J. D. Whitehouse, T. C. D. Whipside, L. R. Whittaker, D. E. C. Whitome, R. H. Whitworth, H. Wickham, R. A. Wilkinson, R. W. Wilkinson, R. F. Williams, A. M. Williamson, C. P. Williamson, H. B. Willington, J. D. Willins, K. M. Willis, D. G. Willson, J. R. E. Wilson, R. R. Wilson, C. A. Wilson-Sharp, D. Wilborne, E. A. Witheridge, J. F. H. Wood, G. R. Wotton, K. A. A. Wray, T. A. Wyllie, P. O. Yates, A. Young, F. R. M. Young, C. E. Phillip, and R. Youngman.

The notification concerning F. Latham in a Supplement to the *London Gazette* dated Jan. 13, p. 270, col. 1, and in the Supplement to the *Journal* dated Jan. 31, p. 21, has been cancelled.

The notifications concerning J. A. B. Mounsey and T. H. Redfern in a Supplement to the *London Gazette* dated Jan. 20, p. 599, have been cancelled.

SPECIAL LIST (EX-INDIAN ARMY)
BRITISH ARMY

Colonels R. L. Vance and Sir G. R. McRobert, C.I.E., have retired.

Lieutenant-Colonels W. McAdam, O.B.E., J. E. Ainsley, and D. H. Waldron, O.B.E., have retired and have been granted the honorary rank of Colonel.

Lieutenant-Colonel W. J. Shipsey has retired on account of ill-health and has been granted the honorary rank of Colonel.

Lieutenant-Colonel R. W. H. Miller has retired.

Majors D. McC. Black and T. P. Binns have retired.

Majors R. K. Muir, F. C. Leach, and O. Walker have retired and have been granted the honorary rank of Lieutenant-Colonel.

Majors L. H. F. Michael and J. H. Cater have retired.

Captains (War Substantive Majors) E. L. Wilson and T. J. Powell have retired and have been granted the honorary rank of Lieutenant-Colonel.

Lieutenant S. N. Eatc has retired.

COLONIAL MEDICAL SERVICE

The following appointments have been announced: J. Boyd, L.R.C.S., L.R.F.P.S., Medical Officer, North Borneo; C. W. J. Hingston, M.R.C.S., and D. F. MacBean, M.B., Medical Officers, Gold Coast; W. J. McGuiness, M.B., Medical Officer, Tanganyika; A. M. Robertson, M.B., Medical Officer, Malaya; C. A. Bathfield, F.R.C.S., Orthopaedic Surgeon, Mauritius; T. A. Doran, M.D., Medical Officer, Fiji; P. Frischmann, M.D., Medical Officer, Nigeria; W. J. L. Neal, M.B., Temporary Medical Officer, Aden; E. S. Shoucair, M.B., Medical Officer, Jamaica; A. H. Barwell, M.R.C.S., Medical Officer, Kenya; D. D. McCarthy, M.B., Assistant Director of Medical Services, Uganda; G. I. Shaw, M.B., Ch.B., Senior Health Officer, Hong Kong; J. R. C. Spicer, M.B., Senior Medical Officer, Vickers, M.R.C.S., Director of Medical, A. McKelvie, M.B., Medical Officer in charge, Gold Coast.

Association Notices

CONSULTANTS AND SPECIALISTS COMMITTEE

Representative of Part-time Consultants' Roll

As a result of a postal ballot held to fill the casual vacancy upon the Consultants and Specialists Committee caused by the resignation of Mr. A. H. Baker, F.R.C.S. (Scarborough), Mr. T. F. R. Griffin, F.R.C.S. (Scarborough), has been appointed to serve on the Committee as a representative of the Part-time Consultants' Roll for the remainder of the session 1947-8.

PRIZES FOR NURSES

The Council of the British Medical Association is prepared to consider the first award in 1948 of three prizes each of the value of 20 guineas for the best essay and three prizes each of the value of 10 guineas for the second best essay submitted in open competition by each of the following categories of nurses: (i) Pupil nurses; (ii) State registered nurses working in a hospital; (iii) State registered nurses not working in a hospital—i.e., district nurses, private nurses, etc.

The subjects of the essays for 1948 shall be: Category (i) "Suggested Improvements in the Methods of Training Nurses"; Category (ii) "Nursing the Patient, not the Disease: the Nurse-Patient Relationship"; Category (iii) "Difficulties of Nursing in the Patient's own Home and their Solution."

The purpose of these prizes is the promotion of systematic observation among nurses. In awarding the prizes due regard will be given to evidence of personal observation. No essay that has previously appeared in the medical press or elsewhere will be considered eligible for a prize. Nurses who are undergoing a course of training at a hospital are eligible to compete under category (i); nurses registered by the General Nursing Council are eligible to compete under categories (ii) and (iii). If any question arises in reference to the eligibility of a candidate or the admissibility of his or her essay, the decision of the Council of the British Medical Association shall be final. Should the Council decide that no essay entered is of sufficient merit, no award shall be made. Each essay must be typewritten or neatly written, must be unsigned, and have attached to it a sealed envelope containing the name and address of the candidate and the category into which he or she falls. Essays must be forwarded to the Secretary of the British Medical Association not later than May 31, 1948. Inquiries about the prizes should be addressed to the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1.

SCHOLARSHIPS IN AID OF SCIENTIFIC RESEARCH

The Council of the British Medical Association is prepared to receive applications for Research Scholarships as follows: An Ernest Hart Memorial Scholarship of the value of £200 per annum, a Walter Dixon Scholarship of the value of £200 per annum, and four Research Scholarships each of the value of £150 per annum. These scholarships are given to candidates whom the Science Committee of the Association recommends as qualified to undertake research in any subject (including State medicine) relating to the causation, prevention, or treatment of disease. Preference will be given, other things being equal, to members of the medical profession.

Each scholarship is tenable for one year starting on Oct. 1, 1948. The scholar may be reappointed for not more than two additional terms. A scholar is not necessarily required to devote the whole of his or her time to the work of research but may hold an appointment at a university, medical school, or hospital, provided the duties of such an appointment do not interfere with his or her work as a scholar.

In addition, applications are invited for the first award of the Insole Scholarship of the value of £250 for research into the causes and cure of venereal disease.

Conditions of Award: Applications

Applications for scholarships must be made not later than Friday, April 30, 1948, on the prescribed form, a copy of which will be supplied on application to the Secretary of the Association, B.M.A. House, Tavistock Square, London, W.C.1. Applicants will be required to furnish the names of three referees who are competent to speak of their capacity for the research contemplated.

CHARLES HILL,
Secretary.

Diary of Central Meetings

MARCH

- 16 Tues. Special Conference of Local Medical and Panel Committees, 11 a.m.
- 17 Wed. Special Representative Meeting, 10 a.m.
- 24 Wed. Council, 10 a.m.

Branch and Division Meetings to be Held

SOUTH-EAST ESSEX DIVISION.—At Southend Municipal Hospital. Rochford (Nurses' Lecture Hall), Friday, March 12, 8.30 p.m. B.M.A. Lecture by Sir Heneage Ogilvie: Some Lessons of War Surgery.

Meetings of Branches and Divisions

EAST YORKSHIRE BRANCH

A general meeting was held on Feb. 11, when Mr. Parkes, biochemist to the Hull Royal Infirmary, gave a lecture on "Some Tests on Liver Function." He discussed the values of the different tests done to assess the function of the liver. He first described the galactose and laevulose tolerance tests, showing how their elimination from the blood stream is impaired with liver damage. He then went on to consider plasma proteins. He next discussed the blood cholesterol, which is increased in amount in obstructive jaundice and decreased in advanced cases of cirrhosis of the liver. He ended by emphasizing that in the investigation of any one case it was necessary to perform a series of tests and to balance the results.

DORSET DIVISION

A meeting of the Division was held on Feb. 17; 39 members were present. Dr. Geoffrey Evans delivered the B.M.A. Lecture on "Some Aspects of Kidney Disease." He spoke on the classification of kidney disease and its treatment, with special reference to Schlemm's diet in the treatment of oedema. He described the uses of the artificial kidney in the treatment of suppression of urine.

LINCOLN DIVISION

A general meeting of the Division was held on Feb. 8 with Dr. A. M. Maiden in the chair. Sixty members and non-members were present.

The chairman put to the meeting the question: "Are you in favour of the National Health Service Act as it stands at present?" On a show of hands 3 were in favour of the Act and 56 were against it. It was then announced that 32 postal votes had been received, and of these 1 was in favour and the remainder against. The total voting of the Division was therefore 4 in favour of the Act as it stands at present and 87 against it.

SUNDERLAND DIVISION

On Jan. 16 Mr. B. W. Rycroft spoke on plastic implants into eye sockets. He then delineated the methods of corneal grafting, and demonstrated with the aid of lantern slides the instruments used. He discussed in detail the technique of obtaining grafts with the trephine and the methods of suturing across the graft to retain it in position; he then considered the post-operative treatment. Mr. Rycroft concluded by showing an American film depicting the technique of corneal grafting by the Castroviejo method.

WHERE ARE WE GOING?

MEDICINE IN A PLANNED ECONOMY

BY

FRANCIS ROBERTS, M.D.

*Honorary Physician in Charge of Douty X-ray Clinic,
Addenbrooke's Hospital, Cambridge*

It is a truism to say that the last fifty years have witnessed a revolution in public health. Many diseases we have exterminated, others we have learnt to cure, others again we have learnt to control; puerperal and infant mortality have diminished, the expectation of life has risen, and the standard of personal, domestic, and public hygiene has improved beyond recognition. Our pride in these achievements, however, should not blind us to the other side of the picture—the rapidly mounting cost of the medical services both in money and in man-power. At any time this remarkable paradox would provide a subject of great

The existence of this increase is of course well known. What is not realized is the acceleration. Figs. 1 and 2 show the rapidly mounting cost per in-patient per week and per out-patient per attendance, respectively, at Addenbrooke's Hospital, Cambridge. The *Hospital Year Book* shows that a similar rise is occurring throughout the country. While it is partly accounted for by the general rise in wages and cost of equipment, it is mainly due to the increase in the amount of work done per patient. In 1897 106 beds were served by four physicians, four surgeons, and two residents; in 1922, with 170 beds, the

FIG. 4.—Number of pathological examinations.

academic interest; in our present economic plight it becomes a matter of grave national concern.

The expansion of medicine is visible to all. With a population almost at its maximum practitioners have increased in the last twenty years by 50%. Many new hospitals have been built and others enlarged and up-graded. Hospital beds, having reached the figure of 600,000, need to be supplemented by a further 200,000. To the increasing army of nurses has been added a large force of auxiliaries which barely existed a generation ago—radiographers, almoners, dietitians, speech-therapists, laboratory technicians, occupational therapists, orthoptists, hospital physicists, masseuses, physiotherapists, child-guidance workers, clinical photographers, records officers, health visitors, and psychiatric social workers—classes which are being added to almost yearly.

total staff numbered 16; in 1947, with 315 beds, it numbered over 70 (Fig. 3). These figures, however, grossly underestimate the increase in man-power, for they take no account of the assistance which the staff now receives from the host of auxiliaries or the greatly increased work done by members of the staff compared with that done by their predecessors, who were mainly occupied with general practice. Although there has been some increase in the population this has been offset by the opening of a new hospital in the area and the enlargement and up-grading of others. In spite of this, demand has outstripped supply, for the waiting-list has risen in the last ten years from 228 to over 1,500. The necessity for the increase in staff will be realized from the increase in the work of one department alone. Since 1927 the total pathological examinations have increased 33 times (Fig. 4) and the blood

counts 50 times (Fig. 5). These figures again underestimate the true increase, since examinations have become more complex. Parallel figures could doubtless be produced by other hospitals. Taking the country as a whole we see in Fig. 6 the rise in the numbers on the *Medical Register*. Twenty years ago the annual increase was 600; it is now

FIG. 5.—Number of blood counts.

FIG. 6.—Numbers on the *Medical Register*.

over 2,000. In fact, whatever medical activity we plot against time we find the same result: *acceleration towards infinity*.

Can we see any sign of a limit to this trend? There are four directions in which we can look: the stabilization of the population, the repair of past neglect, the improvement in social conditions, and the advancement of science.

Stabilization of Population

Since the figures given above show that the rise is mainly due to the increased medical requirements of each patient it is clear that nothing short of a substantial decline in population could operate as a limiting factor.

Repair of Past Neglect

It may be thought that we are making up for lost time and that stabilization will be reached when we have accomplished this task. This, however, is true only to a limited extent. It is a misreading of history to think that our forerunners were neglectful in providing the necessary requirements. Sixty years ago there was barely any need for hospitals, because domiciliary treatment was as efficient as hospital treatment. If we look back we find this general rule: every new development has appeared as a small increment, and its provision has always been regarded *at the time* as amply sufficient for existing needs and a matter for pride and congratulation. When, in 1915, the Governors of Addenbrooke's Hospital built two small rooms for radiology and electrical treatment combined they described the accommodation as "commodious." To-day a floor-space twelve times as great is considered inadequate. At all times estimation of future requirements can be made only in terms of the leeway to be made up and in the light of the existing state of medicine. The developments which are in store, even in the immediate future, are hidden from us. We know neither the form they will take nor the provision which they will need. All we know is that they are certain to come.

Improvement in Social Conditions

The relation between the standard of living and the incidence of disease is complex in the extreme. In theory we should expect a diminution in disease when the whole population is adequately fed, housed, clothed, and educated. In practice, however, several factors operate powerfully to prevent this happy combination. In the first place we have to admit the fact that no causal relationship between social conditions and most of the major diseases which fill the

hospitals. Secondly, as civilization, or at least our conception of it, advances, rational practice becomes complicated by extraneous considerations. There is the threat of litigation and censure, which among its other effects has resulted in the routine x-ray examination of even the most trivial injuries. As the man in the street becomes familiar with the many similar tests which are rapidly being added, the threat of litigation will increase. Now that in almost every family there is at least one person who, being a masseuse, speech therapist, orthoptist or whatnot, is in the best position to speak with authority on medical matters, this threat may reach formidable proportions. Investigations inspired by fear of litigation are inessential by products of the healing art, imposed upon it by modern society. The threat to economy lies not in the premiums paid, nor in the expenses incurred by the protection societies (which can doubtless look after themselves), but in the enormous expensiveness of examinations made not because of their clinical necessity but from fear of savage penalties. The time has come when we simply cannot afford the wholesale radiography of trivial injuries because one in a million may become the subject of litigation. A situation which should be ours to contend with has passed into the hands of the lawyers. The courts will have to accept the plea of reasonable care against accusations based on conventional procedures. Moreover, practitioners are increasingly pressed for the performance of investigations which they know to be useless under the circumstances. Refusal is difficult, since any subsequent calamity will, however unjustly, be ascribed to their obduracy. In private practice concession to prejudice is permissible, since the cost is borne by the patient, but it will be interesting to observe whether, with free medical attention for all, specific methods of investigation will be demanded by patients as a right.

Thirdly, as the standard of living rises people increasingly fail to distinguish between essentials and non-essentials, and tend to judge efficiency by the standard most obvious to them—namely, the *fa-la-las*. I have often heard patients sing the praises of the cottage hospitals (to which they should not have been sent) on account of the homely atmosphere there created. In particular, women value the "dainty teas" in which these institutions specialize. Admission to hospital is coming to be looked upon as a desirable thing in itself, and it is remarkable how this idea has unconsciously crept into common parlance. Recently at a meeting of a friendly society a member complaining of the long waiting-list for admission to the local hospital, said that several hundred members *wanted* to be admitted. A business man in comfortable circumstances and of robust health, speaking of the advantages of the general hospitals over the nursing homes, said he *looked forward* to the time when he could be admitted to a general hospital. At the present time admission to hospital is in many cases essential merely because domestic difficulties make the necessary investigation and treatment impossible to carry out at home. While we may hope that circumstances will improve in course of time, it is to be feared that admission to hospital will meanwhile have become a habit too deeply ingrained to be easily eradicated. If we make hospitals more comfortable than home in inessentials it will be a sign of regression, not of advance in civilization; it will be a reversion to the days when our ancestors found in the monastic infirmaries a refuge from the insecurity of their wattle huts. In short, whatever reasons may exist for hoping that a rise in the standard of living will diminish the incidence of disease, there is every reason to fear that it will increase the incidence of treatment.

The Advancement of Science

The most reasonable hope for the diminution of disease may seem to lie in the advancement of science. The astonishing growth in our knowledge about the natural history of diseases is, however, no measure of the speed at which we are finding the causes of disease. Medical research is peculiarly obedient to the law of diminishing returns. In the first place, unlike most other sciences, which stretch forth into a boundless ocean, its sphere is very definitely circumscribed. In the last resort it is up against the inevitable; its concern is the postponement of a natural termination, and it is significant that in the new science of geriatrics we are interesting ourselves in the consequences of such postponement. We live in an age of increasingly

medicated survival. Secondly, our most dazzling successes have concerned those noxious agencies which differ biologically from, are extraneous to, human life rather than those which resemble or are inherent to it. Hence our triumphs have been greater over acute than over chronic ailments. Progress slows as we come to deal with the weaknesses of the flesh. The discovery of vaccination, though undoubtedly a stroke of genius, is a simple matter suited to the crude state of science then existing. Profound as was its effect upon society, the conquest of smallpox was achieved at a cost which was infinitesimal compared with to-day's expenditure on cancer research. Thirdly, humanitarianism, while being the main inspiration of medical research, at the same time imposes upon it severe limitations. While urging us to the strife it withholds from us the use of the most powerful weapons—wholesale slaughter and breeding from immune strains—which have proved so effective and economical in the hands of the agriculturist. For these reasons medical research has, of all forms of research, the least prospect of reaching its ultimate aim.

If this view appears unwarrantably pessimistic let us appeal to the facts and consider the effects of the fruits of research upon everyday clinical practice. Of the hordes of diagnostic tests in common use very few are, like the identification of the tubercle bacillus in the sputum, discoveries of the cause of disease. By far the greatest number are tests of consequences—tests, that is to say, of the reaction of the body to some infection or disturbance of unknown nature. For the most part these tests, however valuable they may be diagnostically, only determine by-results which are brought to light by scientific and sometimes fortuitous means. They are like the flotsam which, unseen in the roaring torrent but readily visible in the eddying pools, merely indicates that some disaster has occurred nearer the source. These tests have come to be used not merely to confirm a clinical diagnosis and to settle a matter of doubt but also to discover morbid conditions alleged, on grounds however uncertain, to be responsible or associated. Witness the tests required to discover or eliminate foci of infection said to be the cause of fibrositis. They are used to make a diagnosis doubly and even trebly sure, and to prove the absence of any other diseases—a process which multiplies as new diseases, new modifications of diseases, and resemblances between diseases are discovered. We dare not make a diagnosis of neurosis without using all the appropriate tests to eliminate beyond all shadow of doubt the organic diseases which it simulates, and with each test the patient becomes increasingly impressed with the reality of his complaint and prouder of its importance. Moreover, these tests are also employed at frequent intervals to gauge and control treatment, for the therapeutic seas into which we now venture are navigable only by the most vigilant flotage of the laboratory. The truth is that, at any rate in regard to chronic disease, cure is being more and more outstripped by treatment, and there is no sign that the situation will be reversed.

This prospect, ominous enough in itself, is rendered more ominous by the disturbing fact that advancing knowledge so often obscures rather than clears our vision. For many years radiological examination was held to provide reliable evidence of the existence or absence of a gastric ulcer. But now it is aimed that gastroscopy reveals ulcers invisible to radiology. It is the result, recorded in the *British Medical Journal* of Aug. 9, 1947 (p. 215), of an experiment in which the same x-ray films of the chest were submitted to five radiologists.

"The number of the full-size celluloid films found positive for tuberculosis varied from 59 to 100; altogether 131 films were described as positive. All five agreed that the film was positive in only 27 cases. Four were in agreement on 17 films, three on 17, two on 23, and in 47 cases only one observer described the film as positive. Further individual comparisons showed that from one-third to one-half of the films described as positive by one reader were negative according to the others. The radiologist with the smallest group of 59 positives had 31, 29, 37, and 14% of his positive films described as negative by the other four. The proportion of another reader's 100 positives labelled negative by the other experts varied from 42 to 50%.

The failure of the same individual to be consistent in judgement was even more astonishing than the variation

between different radiologists. All the films were assessed for a second time at a later date by the same five readers. The proportion of first positives regarded as negative on second reading by the same expert varied from 7 to 41%, and the proportion of the second positive readings which had been called negative on a first reading ranged from 6 to 19%. The radiologist who had 59 positives originally found an additional 23 on his second assessment, but missed 4 of his own first positives."

This makes depressing reading. We are left with the impression that modern methods, with their mounting cost and complexity, while valuable in establishing a diagnosis already made by simpler means, contribute little to the elimination of doubt and uncertainty. Scientific discoveries hailed on their first appearance as fresh triumphs over Nature lead to disillusion when their limitations are realized. Artificial aids to our senses make the boundary between health and disease vaguer instead of clearer. Does our reliance on them denote a lack of faith in ourselves? Does it mean that, in the words of H. G. Wells, mind is at the end of its tether? It is like the problem of the fens. The more these are drained, the deeper they sink, and the deeper they sink, the more they have to be drained, so that a time may come when the cost of drainage exceeds the value of the food grown on them.

If I appear to decry the value of research and to advocate empiricism let me say at once that nothing is further from my intention. There is a world of difference between the discriminating application of research on the one hand and, on the other, the routine performance of its technique by the unskilled and the self-confident interpretation of its results by the inexperienced. If a tree produces too much leaf we can, by ringing the bark, pruning the roots, or other device, restrain the sap and at the same time direct it to fruit-formation. Economic factors may force us to confine the prolific sap of science, without affecting its source, to the most productive channels. While encouraging genius we must make it clear that medicine is no place for the career-plugging of mediocrity.

The Fetish of Perpetual Expansion

We have unfortunately come to accept expansion as inevitable and unending. Nobody even visualizes a time when our hospitals will be emptied instead of crowded, when the conquest of disease will lead, as it logically should, to the diminution of disease. We go further and seem to assume that such expansion is something desirable in itself. We pride ourselves on the cultivation of virgin soil rather than on the harvest. Consider, for instance, the plans recently envisaged for the development of clinical photography (within certain limits a desirable thing). According to one of its enthusiastic advocates the department of the future must have a medically qualified director, an assistant director, two photographers who must also be trained nurses, a microscopist with additional training in photomicroscopy, a secretary, an instrument mechanic, a nurse, and a porter. Accommodation must consist of one large main studio, 40 by 20 ft. (12.2 by 6.1 metres), three subsidiary studios, 15 by 10 ft. (4.8 by 3 metres), three small studios for the photography of small objects, seven dark- and accessory-rooms, a secretary's office, a filming-room, a director's room, dressing cubicles, linen-cupboards, lavatories, storerooms, and a small surgery. This, we are told, would suffice for the first three years; after that extensions would be necessary. Among the users of the department would be the welfare department, which would wish to "show the return of a healthy glow to the cheeks of a convalescent." A second enthusiast tells us that medical photography must become "a subject in our medical schools on an equality with radiology." A third tells us that the staff will need a lengthy and complete training. Spaciousness, he says, would be necessary in order to counteract "the demoralizing effect of cramped quarters." But, one may ask, were Louis Pasteur, J. J. Thomson, and Gowland Hopkins demoralized by the cellars in which their best work was done?

This is perhaps an extreme case, but it illustrates an attitude of mind from which many of us suffer. Ambition in its most virtuous form impels us to raise ourselves higher from the ground on a pyramid of ever-increasing subordinates and accommodation. We measure our success by the material growth of the things which we create, forgetting meanwhile that in many human activities, such as increase of population and exploitation of new countries, this standard has had to be abandoned. We see limit, either actual or implied, in all directions; in the wide adoption of birth control, in the world shortage of many necessities, in the control of entry to the universities, and in the predetermination of the size of the new satellite towns. We can therefore hardly maintain our faith in the inevitability of perpetual expansion in the one feature of social life whose reduction is essential to the prevention of the reduction of everything else.

The Dependence of Medicine on Economics

The idea that medicine is immune from economic laws is fostered by several factors. First, in a commodity the need for which diminishes the capacity to pay for it the laws of supply and demand cannot operate. The cost of treatment having for the great majority of the population been removed from the sphere of domestic economy and transferred first to charity and later to the State, the consumer is a third party (the doctor) who, acting in the interests of the recipient (the patient), has therefore no interest in economic considerations. Spending all he is given, he appeals for more to the supplier, who is totally incapable of judging the degree of necessity.

Secondly, life is not, as it is sometimes believed, beyond price under all circumstances. Its value increases with the danger which threatens it. When the danger is imminent people are quite unreasonable; when involved in an accident they expect doctors and nurses to appear out of the blue. The great majority of the community have in fact set the value of their lives at a very low figure, for the 4d. or 6d. per week which is the most that can be extracted from them for specialist treatment under the contributory schemes is only a very small fraction of their expenditure on the cinema, football pools, and cigarettes. That the value of life is only relative is easily proved. The appalling toll of road accidents could be reduced to vanishing-point by a decree limiting speed to 10 miles an hour. We do not take this step because it would dislocate our commerce and (let us be candid) curtail our pleasure; we prefer to improve the treatment of the results of accidents.

Thirdly, in the healing art the heart as well as the head plays a part: it cannot be conducted in the matter-of-fact manner with which we cash a cheque at a bank. Patients have strong views of their importance and behave as though the world revolved around them. The public, while granting that the medical labourer is worthy of his hire, believe that under certain circumstances, such as a railway accident, humanitarianism must override financial considerations. Humanitarianism is, moreover, mixed with sentiment—a commodity which, however inexpensive and harmless it may appear, may have costly reverberations. When food distributors go on strike but graciously make an exception in favour of hospitals they make a bid for sympathy as illogical as it is mawkish. For the crocodile tears which they shed for the sick in hospital blind them to the sufferings of the sick in their homes, not to mention those awaiting admission to the hospitals and those recently discharged and in need of special nourishment. They overlook, too, the ill-health consequent upon the deprivation of food of which they are the cause.

The Economic Background

Since we can see no sign of any arrest of this accelerating expansion (let alone any reversal of the process) in stabilization of the population, in repair of past neglect, in improvement of social conditions, or in the advancement of science, and since such expansion is clearly incompatible with a contracting economy, we are forced to conclude that the limit will be determined by the available resources of man-power or cost, or both. The limit in man-power is already evident in the acute shortage of nurses, and shows signs of spreading to other sections. Improvement in the conditions of employment, however desirable, is no solution, for it only increases the cost and probably attracts less suitable entrants. Moreover, the labour market being limited, the shortage can be relieved only at the expense of productive work. As regards the cost, we must bear in mind that with the establishment of the National Health Service the State becomes a single *private* patient—John Bull. But whereas the individual private patient can deny himself the benefits of medical treatment or throw himself upon charity if the cost is beyond his means, John Bull must foot the bill. The question is, How much can he afford to pay? The answer depends upon three stark economic truths.

First, disease cannot be anything but a tax on national prosperity, however much it may benefit sections of the community. Secondly, the available resources, whether national or charitable, are only two—the surplus of agricultural produce and the surplus of exports over imports. In this country the first of these has long ceased to exist, and cannot return unless the population is substantially reduced. The absence of the second is now only too painfully apparent, but many still fail to realize that it is something far greater than a sudden and temporary calamity. It was predicted by Disraeli in 1847, and in view of the increasing industrialization of other countries it is extremely unlikely that we shall even approach the high-water mark reached on that day fifty years ago when the captains and the kings departed.

The third truth is that the standard of medical treatment is influenced by, and at the same time influences, the general standard of living. This reciprocal relationship arises from the fact that the purpose of medicine, which is the promotion of happiness and prosperity by the subjugation of ill-health, consists of two components, humanitarian and economic. Though these are interwoven in practice we must for our present purposes separate them. The humanitarian component is uppermost in the relief of suffering in the aged and infirm, though the economic component is also present if this relief is accompanied by a reduction in the number of those in attendance upon the recipients and their consequent liberation for productive work. The resources available for the humanitarian component are limited by personal or national income. What we can afford to spend may, and often does, fall short of what we should like to spend. This is a hard saying, but we live in a hard world.

Suppose that 100 patients suffer from a rare disease curable only by the use of a drug costing £50,000 per patient and that there is no prospect of this amount being reduced. The £5,000,000 required to save these lives would clearly be beyond the resources of the State, for it could be provided only at a sacrifice which would involve loss of efficiency and therefore loss of health to the whole community. As the State could hardly make an exception in favour of one patient no one would be saved. If, however, one patient were a millionaire he could save himself by writing a cheque for the amount. This hypothetical case

may seem fantastic, but it is only an exaggeration of what actually occurs. Recuperation in the South of France can be enjoyed by the few but is denied to the average citizen, although he is glibly promised the finest medical service in the world. Of the rare and refreshing fruit promised by Lloyd George not a single grape has assuaged any parched lips from National Health resources. A medical service provided by the State cannot be as efficient as that which the fortunate few can provide for themselves. In a beleaguered city there is a limit to which the defenders can share their rations with the infirm. If that limit is overstepped by dictates from the heart the defence is imperilled. The fear that we may have reached the danger mark is in the minds of those who now question the wisdom, from the national point of view, of the liberal allowance of milk to sufferers from dyspepsia. In regard to its humanitarian component, then, the standard of a national medical service is limited by the general standard of living. It cannot overstep that limit without adversely affecting national prosperity.

In the economic component the situation is the reverse, for here the standard of medicine directly influences the general standard of living. This component is typified in the youth who submits to the radical cure of hernia in the hope of the financial reward which will ensue from his increased efficiency. The benefit will not be confined to himself but will be felt by the whole community. Personal good becomes merged into national good. This fact indicates the amount which the State can afford to spend on the economic component. It must be less than the value of the improvement which is expected to accrue. It must show a profit in the long if not in the short run. We are often told of the annual loss of labour, expressed in man-hours, due to minor ailments, and the figures are indeed formidable. If this wastage can be reduced by research carried out centrally and capable of cheap application peripherally there is an economic gain. But if we rely on uncoordinated and ill-considered peripheral action the result may well be an economic loss. If, for instance, a hospital contemplates the establishment of an auxiliary service devoted to the economic component, the reason must be economically sound. It is not sufficient to say that other (probably larger) hospitals are doing it, nor can the question, "Can we afford to do it?" be met by the fatuous rejoinder, "Can we afford not to do it?" if by his is meant, "Can we countenance the loss of prestige if we don't?" Nor, again, is the step justified if, when established, the department is used because it is there, not because it is really needed. It may be justified in three ways. First, the improvement in treatment must result in an improvement in national efficiency—in the more rapid return of the worker to industry and in a lessening of expenditure on man-power in attendance upon patients after their discharge from hospital. Secondly, the work of the medical staff must be eased so that it can deal with the same number of patients in a shorter time, with the ultimate object of making fewer doctors necessary. Thirdly, research into the causes and treatment of diseases which reduce working capacity must be thereby facilitated. This admittedly a difficult criterion; it is sufficient here to state that it is applicable to only a few hospitals.

While I fully appreciate that in practice the humanitarian and economic motive cannot be separated, I am convinced that we cannot solve the problems which confront us unless we realize that national prosperity determines the humanitarian component and is largely determined by the economic component. The importance of the economic component is brought home to us only when man-power is short. Always implicit in the work of the military medical services, it is forced upon us for the first time during peace

by the stark reality of our plight. We must constantly bear in mind that every person engaged in medicine is a person lost to the production of food and exports. Medicine is now not only a humanitarian profession but also an indirectly productive trade.

Conclusions

If my philosophy appears unduly pessimistic my answer is that economics is notoriously a dismal science and cannot be otherwise when applied to medicine. Those who think that medicine is above economic laws are destined to have their illusion rudely shattered, for a limited and planned economy obviously cannot support a health service expanding with the acceleration which medicine now exhibits. I do not pretend that the suggestions which I have made touch the main problem: still less do I expect them to command universal assent. I shall be content if I have succeeded in stimulating a realization of the situation and the disastrous consequences of ignoring it. I foresee three dangers which are by no means remote. First, money and labour will be spent on trifling ailments to the detriment of those who are seriously ill. There are indeed signs that we have already reached this stage. My realization of this danger will, I hope, absolve me from any charge of displaying in what I have written an unsympathetic view of ill-health. Secondly, individual attention and mature thought will be replaced by routine performance and reflex automatism. Responsibility beyond their capacity will be delegated to subordinates and auxiliaries, with the encouragement of that form of self-confidence which never admits ignorance. The maintenance of a high standard of practice will be greatly imperilled. Thirdly, the threat to freedom of action in our dealings with patients, a threat which we so much dread, may be forced on us not by a thirst for official control but by sheer economic necessity. When limitation becomes imperative, as it certainly will, it is surely preferable that it should be self-imposed by those who have an intimate understanding of the subtleties of clinical medicine rather than enforced by those who have only a bureaucratic acquaintance with it. In the reconstruction of our distracted world the doctor will be called upon to play a vital part, a part transcending the mere technicalities of his profession, a part which will demand, as never before, the fullest exercise of his intellectual qualities and moral influence. We rightly dread any violation by the State of the sanctity of the doctor-patient relationship, but the preservation of this sanctity depends upon the full recognition by doctor and patient alike that individual health and national health cannot be dissociated, and that intelligent but at the same time unselfish regard for his own health is not the least contribution which every citizen must make to national prosperity.

Chiropody. Theory and Practice (3rd edition, Charlesworth and Wiles, 42s.), by Franklin Charlesworth, is already well established as a useful textbook among students and practitioners of chiropody. The issue of a third edition, largely rewritten and extended, shows that it meets a demand which is likely to increase with the growth of the auxiliary medical services, including chiropody, when the Health Service starts. If the new entrants to the profession absorb all the information and carry out the precepts given in this book they will indeed become worthy practitioners, for as its title implies it is a most comprehensive production ranging over anatomy, physiology, surgery, medicine, materia medica, and theoretical and applied chiropody. However, the author has been at some pains to determine that of such vast subjects only those aspects which are of direct interest to the chiropodist have been included. The student will find here just the information he requires to cover his examination syllabus. The medical practitioner who sees and is interested in minor foot disabilities will discover much useful guidance in this volume on the possibilities and limitations of chiropodial treatment. The book is well and clearly illustrated and the production is of a high standard.

THE HEALTH OF 407 NEW STUDENTS

BY

JOHN PEMBERTON, M.D., M.R.C.P.

(From the Department of Medicine, University of Sheffield)

The publication of three recent reports on the problems of student health indicates a growing interest in this subject. Investigations have been made by the British Medical Students Association and other student bodies (1944), the Social and Preventive Medicine Committee of the Royal College of Physicians (1946), and the Conference on Student Health organized by the Nuffield Foundation (1947). These reports call attention in general terms to the existence of a good deal of ill-health among the student population and point to the need for better facilities for dealing with it. So far, however, little detailed information has been published on the nature and extent of this ill-health.

Voluntary medical examinations for students entering the University of Sheffield were introduced in 1937 and made compulsory for all new students in 1942. The aim of the medical officers who conduct these examinations in the students' first or second term has been to discover any remediable cause of ill-health and to advise them on how to obtain the appropriate treatment.

The present report describes the state of health of a group of 407 students admitted to the University in October, 1946. In addition to the medical data, certain aspects of the students' social environment are discussed in their relation to health.

Methods

The general medical examinations were conducted by a team of medical first assistants, the dental examinations by the dental registrar, and the ophthalmological examinations by the ophthalmological registrars from the Royal Sheffield Infirmary and Hospital. In addition, the woman students had a haemoglobin estimation and the medical and dental students a full-sized chest radiograph. All the students had a private "health interview" with me at the end of the various examinations. At this interview any defect or disorder requiring treatment was discussed and the student was referred to his general practitioner or, sometimes, if he had no doctor in Sheffield, to the out-patient department of the Royal Sheffield Infirmary and Hospital. During the interview a family health history was obtained and questions were asked about the student's lodgings, travel to the University, recreations, work, and sleep.

Classification of Students

In presenting the results the male students have been separated into two groups: 157 students aged 20 years and over, nearly all of whom were ex-Service men, and 153 students under 20. This separation has been effected because the ex-Service group do not constitute a normal student population and have special socio-medical problems, as is shown later. The 97 women students have not been included, as only 18 were aged 20 years and over. There were 372 British students, 24 European, and 11 non-European.

In order to discover whether the health of the students was related to their previous social environment the records were classified according to the father's occupation. The Registrar-General's classification (1944) was adopted—Group I, professional and upper managerial; Group II, lesser professional and managerial, retail proprietors, etc.; Group III, black-coated workers and skilled artisans; Group IV, semi-skilled workers; Group V, unskilled labourers; Group VI, unclassified; Group VII, Non-European.

Table I shows the constitution of the student group by age, sex, and occupational category of the father. The largest proportion of students (34%) were from Group III.

TABLE I.—Age, Sex, and Social Groups of the Students

Social Group (Father's Occupation)	Men Under 20 (153)	Men 20 and Over (157)	Women (97)	All Students (407)
I Professional and upper managerial	15%	10%	19%	14%
II Lesser professional, retail proprietors, etc.	25%	25%	29%	26%
III Black-coated workers and skilled artisans	41%	27%	35%	34%
IV Semi-skilled workers	10%	2%	2%	5%
V Unskilled labourers	3%	2%	2%	3%
Unclassified	6%	27%	11%	15%
Non-European	—	7%	2%	3%

Only in the men under 20 was there an appreciable proportion (13%) from social Groups IV and V. The women students tended to come from a slightly higher economic stratum than the men.

The Findings Analysed

Table II shows the chief causes of defective health found in the new students.

TABLE II.—Chief Causes of Defective Health

Type of Disorder	Men under 20 (153)	Men 20 and Over (157)	Women (97)	All Groups (407)
Dental caries requiring treatment	75%	65%	76%	73%
Defective vision: corrected with glasses or needing correction	36%	36%	35%	37%
Postural and other orthopaedic defects	38%	27%	40%	34%
Minor anxiety states or depression	16%	29%	16%	20%
Nervous breakdown, marked introversion, psychoneurosis, epilepsy, hysteria, schizophrenia	8%	6%	7%	7%
Ear, nose, and throat: chronic nasal obstruction, sinusitis, enlarged or inflamed tonsils, partial deafness, discharging ear	20%	24%	25%	23%
Skin diseases: acne, furunculosis, epidermophytosis, eczema, dermatitis	13%	6%	7%	9%
Pulmonary disease: bronchitis, bronchiectasis, pulmonary fibrosis, asthma, emphysema	6%	4%	3%	4%
Endocrine disorders: enlarged thyroid, hypogonadism, obesity, undescended testicle	6%	2%	6%	5%
Cardiovascular disease:				
Mitral stenosis	2%	1%	1%	1%
Essential hypertension	2%	2%	—	1%
Hypochromic anaemia (under 85% Haldane)	—	—	3%	—
Miscellaneous: varicose veins, dyspepsia, migraine, varicocele, hydrocele, hernia	1%	3%	5%	2%

Dental Caries.—This was easily the most common disorder—73% of all the students required treatment for this condition. A smaller proportion of the ex-Service group required treatment—65% compared with 75% and 76% in the other two groups. This did not reflect a lower attack rate of dental caries among the ex-Service group, but a greater amount of previous dental treatment. The attack rate, obtained by adding to the number of students with active dental caries those who had fillings but no caries, was 96% in the men under 20, 98% in the men 20 and over, and 93% in the women. The attack rate of dental

TABLE III.—Showing the Relationship between the Incidence and Extent of Dental Caries Requiring Treatment and the Social Grouping

Social Group	No. in Group	Incidence of Active Dental Caries	Average No. of Fillings Needed per Mouth	Average No. of Extractions Needed per Mouth
I	55	72%	1.45	0.60
II	107	74%	2.50	0.29
III	132	72%	2.20	0.34
IV and V	30	83%	3.50	0.87
Unclassified	62	59%	2.66	0.61
Non-European	11	55%	1.34	0

caries did not vary significantly from one social group to another, but both the incidence of untreated caries and the extent of the disease increased in the lower economic groups (Table III). It seems probable that financial considerations had prevented some of the students from the poorer social groups from obtaining dental treatment. The dental condition of the non-Europeans was better than that of any of the other groups.

Visual Defects.—Defective vision was second in order of frequency: 36% of the whole group had myopia, 31% had hypermetropia, and 3% had mixed astigmatism. In 37% (150 students) the defect was such as to require spectacles for its correction. Of these 150 students 100 were already wearing correct spectacles, 40 had incorrect spectacles, and 10 had no spectacles. There was no relationship between the incidence of visual defects and social grouping.

Orthopaedic Defects.—Some orthopaedic defect was present in 34% of the students. Most of these were postural defects of the spine or flat-foot. Their incidence is shown in Table IV. Postural spinal defects were commonest in

TABLE IV.—Incidence of Different Types of Orthopaedic Deformity

Orthopaedic Abnormality	Men under 20 (153)	Men 20 and Over (157)	Women (97)	All Students (407)
Minor spinal deformities (scoliosis, kyphosis, lordosis)	22%	12%	15%	16%
Flat-foot	13%	10%	18%	14%
Miscellaneous	10%	7%	19%	12%

the men under 20 and flat-foot was commonest in the women students. Two students had orthopaedic defects requiring operative treatment. Most of the orthopaedic abnormalities found were due to lack of muscle tone and physical development, and could perhaps have been prevented by better previous physical education. They emphasize again the value of adequate and easily available facilities for athletics, sports, and gymnastics as a positive contribution to student health.

Mental Health

In the reports already mentioned attention has been drawn to the frequency with which minor psychological disorders are found among students. The present investigation confirms this. All the assessments of mental health were made by me after interviewing each student. Variations in assessment due to the personal factor were therefore minimized. Some 20% were found to be suffering from minor anxiety states or depression. Table V shows that the incidence of anxiety was remarkably similar in the three main groups of students.

TABLE V.—Anxiety States and Depression (mostly minor in degree)

	Men under 20 (153)	Men 20 and Over (147)	Women (95)	All Students (395)
Anxiety states	15.0%	16.3%	14.7%	15.4%
Depression	0.7%	12.3%	1.05%	5.05%
Total	15.7%	28.6%	15.75%	20.45%

It is worth while to consider the possible causes of these anxiety states. The occupation of the student is unique so far as it is probably the only one in which those who follow it are repeatedly subject to formal tests of their fitness to continue the work. Fear of failing to pass these tests of "fitness" provides one of the main psychological stresses to which students are subject. For the present generation, further penalties may be added to examination failure, such as the loss of grants, calling up for national

service, and the end of a university career. One of the manifestations of anxiety recorded was the presence of insomnia. This was marked as present if the student lay in bed more than an hour before he went to sleep or if he habitually lay awake in the night for an hour or more—34 (9%) had insomnia of this degree.

A large number (28%) of the students were "only" children, and the proportion of these increased steadily from the higher to the lower economic groups (see Table VI). It would appear that among children from

TABLE VI.—"Only" Children

Social Group	No. in Group	Percentage of Only Children
I	52	11.5
II	93	27.5
III	134	34.2
IV and V	30	59.0
Unclassified	53	13.8
Total	357	23.3

poorer families those without brothers and sisters have a better chance of reaching university than those from larger families. This type of student—the only child from a poor family—is especially likely to feel a heavy burden of responsibility and indebtedness towards his family which may add to his anxieties.

The following excerpts from the students' health records briefly illustrate how some of these anxiety states in students can develop.

A. B., aged 18. Father died 10 years ago. Mother goes out to work; one brother and one sister. States he is "worried about getting thrown out" if he fails his exams. Works every evening, including Sundays.

C. D., aged 28. Was in Services for 6½ years. States he has no time for recreation. Suffers from insomnia; takes an hour to get off to sleep. "It's all this studying. It's a strain getting back to work again after all this time in the Army."

E. F., aged 33. No time for recreation. "I'm not letting up on myself: I've got to complete this course. I work on at night till I can't work any more."

Depression was twelve times as common in the ex-Service group as in the other two groups of students. The interviews suggested that the chief cause of the relatively high incidence of depression in the ex-Service group was the difficulty these students experienced in adjusting themselves to civilian life. Many of them had occupied active and important positions in the Forces, and some were not unnaturally dissatisfied with what seemed to them the relatively unimportant role of a university student. Of the ex-Service group 25% were married, and half of these had children. To these responsibilities were added the difficulties associated with finding accommodation for their families in or near the city.

In addition to the cases of mild anxiety states and depression eight students were diagnosed as psychoneurotics, two as hysterics, 14 were markedly introverted, one had had a recent nervous breakdown, one suffered from epilepsy, and two showed evidence of early schizophrenia. Many of the students with the minor anxiety states and depression will probably lose these as they become adapted to university life and succeed in proving to themselves that they are adequate for the tasks before them. It is among the psychoneurotics and schizophrenics that the long-term problems are to be found.

Organic Disorders

Organic defects and disorders have been classed as major if they were considered likely to prevent the student from participating fully in university life, and minor if they were not sufficiently serious to do that.

Some major organic disorder was found in 9%, and in this group pulmonary conditions were the most frequent, accounting for nearly half. Five students had chronic bronchitis, five asthma, four bronchiectasis, four pulmonary fibrosis, and one emphysema. Most of the group stated that their illness had started with a previous attack of pneumonia. They illustrate the chronic invalidity which too often follows this disease. Next in importance came the group with cardiovascular disease. Four students (1%) had mitral stenosis and four had essential hypertension (blood pressure 150/100 or above). It is worth recording that 35 students (9%) had innocent cardiac murmurs and three had persistent albuminuria for which no cause could be found. No case of pulmonary tuberculosis was discovered among the 76 medical and dental students who underwent chest radiography or in the remaining 331 students at the general medical examination.

Among the women students and men under 20 major organic disorders were more common in those from the lower economic groups than in those from the higher groups. The men over 20 were of course a physically selected group. Six of the 19 men under 20 (33%) from social groups IV and V suffered from a major organic disorder, compared with 9% in the whole group of students. Of these six students two had mitral stenosis, one bronchiectasis, two chronic bronchitis, and one asthma.

In 40% a minor organic disorder, excluding dental caries, defective vision, and orthopaedic conditions, was found. These mostly consisted of affections of the ear, nose, and throat, or of the skin. Some 23% suffered from chronic nasal obstruction, sinusitis, enlarged or inflamed tonsils, partial deafness, or discharging ear; 9% had skin conditions such as acne, furunculosis, epidermophytosis, eczema, or dermatitis. These skin conditions occurred twice as often in men under 20 as in the other groups (Table II).

The average haemoglobin value of the 95 women tested was 98.6 (Haldane). Three cases of hypochromic anaemia were found, however, with values of 68, 80, and 84. After treatment with iron for six to seven weeks these values became normal—102, 96, and 102% respectively.

Examples of minor disorders of the endocrine glands were not uncommon, especially in the younger groups: 6% of the men under 20, 6% of the women, and 2% of the ex-Service group had conditions such as diffuse enlargement of the thyroid, hypogonadism, obesity, or undescended testicle. There appeared to be no relationship between the incidence of minor disorders and social grouping.

Conclusions

A considerable proportion of the 407 students examined had some physical or psychological defect or disorder. Although in most cases these disabilities were not serious, they were sufficient to reduce the efficiency and well-being of many students. The findings indicate that in the development of student health schemes, in addition to medical examinations of new students, provisions for the active medical treatment and supervision of university students need consideration. The high incidence of dental disease and defective vision points to the need for special provisions with regard to these conditions. A medical officer in charge of student health may expect to be frequently consulted by students on account of anxieties often disguised by some physical complaint such as vague pain in the chest. If he is to treat them successfully it is essential that he should be interested in them not only as patients but also as individuals who are developing rapidly and are not infrequently subjected to considerable physical and psychological strain.

The treatment of postural and other orthopaedic defects is the question of the value of compulsory physical

education such as has been introduced for freshmen in at least one British university: Routine haemoglobin estimations on women students followed by treatment of the cases of hypochromic anaemia discovered is a worth-while procedure.

There will probably always be students who enter university with serious and permanent physical handicaps such as mitral stenosis or bronchiectasis. A students' health service and the initial medical examinations should not be used to exclude such students, but rather by advice and careful supervision it should enable them to make the best use of their university career.

Finally, student health centres could become valuable field stations for university departments of social medicine. In them, for example, studies of normal variations in structure and function could be made, and methods developed for the early detection and prevention of disease in the young adult population.

Summary

The results of the compulsory medical examinations of 407 new students are presented.

Dental disease, defective vision, postural faults, and minor psychological disorders were the commonest conditions found.

The various factors contributing to the development of anxiety and depression in students are discussed together with some aspects of the students' social environment.

The need for the further development of student health services to include the provision of medical and dental treatment when required is re-emphasized.

I wish to thank all those whose careful observations and records made this study possible. The general medical examinations were carried out by Drs. R. Rosenberg, F. Flint, R. T. Gaunt, J. F. Goodwin, L. Nancekivell, M. H. Stewart, and W. D. Wallace; the ophthalmic examinations by Drs. W. Ingman, M. W. Paterson, A. Smith, and N. S. Warwick; the dental examinations by Mr. R. Rastall; the radiological examinations by Drs. J. L. Groul and J. Wilkie; and the haemoglobin estimations by Dr. H. J. Barrie. I am indebted to Prof. C. H. Stuart-Harris for helpful suggestions; to the authorities of the University of Sheffield for permission to publish this report; and to Miss B. I. Richardson, who gave valuable assistance in its preparation.

The second edition of Mr. Harry Hill's *Pasteurisation* (H. K. Lewis, 21s.) is to be welcomed. Most of the faults of the earlier edition have been remedied, and numerous illustrations and figures have been included to clarify the sections on plant design and control. The size of the book has been nearly doubled. There is an interesting description of the Hemming-Howell heating unit for the treatment of milk churns on the farm, though it would be interesting to know more about the effectiveness of this method under practical working conditions. Like most idealists, the author favours the adoption of the "in-bottle" method of pasteurization, and he forecasts the adaptation of the H.T.S.T. process to the heat treatment of milk in bottles. Whether he is on such safe ground in recommending the increased use of irradiated milk is more doubtful; the possible danger to adults of consuming unlimited quantities of vitamin D is not considered. This book can now be recommended without hesitation to those who want to learn something about the methods of carrying out pasteurization and the subsequent treatment of pasteurized milk. It is, however, alarming to be told in the preface and again on p. 229 that "all methods of pasteurization carried out in this country are not satisfactory." This general condemnation is surely unjustified, and we hope that what the author really means is that not all methods of pasteurization are satisfactory. Perhaps an alteration to this effect might be made in the next edition.

THE RECOGNITION OF TOXICOGENIC BACTERIAL STRAINS IN VITRO

BY

STEPHEN D. ELEK, M.D., D.P.H., D.C.P.

(From the Department of Bacteriology, St. George's Hospital Medical School)

The detection of toxicogenicity *in vitro* has not in the past proved a practical proposition for routine purposes, and this paper is concerned with a new technique which, it is believed, makes this possible. In diagnostic bacteriology most pathogens are recognized by their cultural and biochemical properties, and are finally characterized by serological study of their antigenic structure. In those groups of organisms which produce disease through the agency of exotoxins the surface antigenic pattern is of little diagnostic use, and final recognition is effected by specific serological neutralization of the toxin in a susceptible experimental animal. Clearly a rapid test is required to bring exotoxin-producing organisms into line with those which can be identified serologically. Technical difficulties have, however, prevented the use of *in vitro* toxicogenicity for diagnostic purposes. The lecithinase action of the alpha toxin of *Clostridium welchii* is an exception to the rule that toxins rarely produce convenient effects *in vitro*. Flocculation of diphtheria toxin with its homologous antitoxin was first demonstrated by Nicolle, Césari, and Debains in 1920 and is widely used for titration of antitoxin (Ramon, 1922), but the procedure in its original form is too complex for routine identification of toxicogenic strains.

Petrie and Steabben (1943) introduced a technique for the identification of the pathogenic clostridia of gas-gangrene in plate cultures. Crude specific antitoxic serum was incorporated in an agar-base medium designed to yield abundant toxin production. After prolonged anaerobic incubation the plates were left at room temperature, and under these conditions a ring of opacity developed around the colonies of a toxicogenic strain in the presence of the homologous antiserum. The zone of opacity was shown by the plate microscope to consist of Liesegang rings, and was accepted as a specific reaction.

The same workers attempted to employ this technique for the recognition of toxicogenic strains of *Corynebacterium diphtheriae*, but the results were unsatisfactory. Repetition of their experiments suggested to me three main reasons for the failure. In the first place, isolated colonies produce only minute amounts of toxin even after prolonged incubation. Secondly, as flocculation occurs only within a narrow zone, and as both toxin and antitoxin excess may inhibit the reaction, it is necessary to adjust the antitoxin content of the plate most carefully; strain variations in toxicogenicity make it very difficult to gauge the antitoxin concentration so as to be within the optimum range. Thirdly—and this is perhaps the most serious difficulty—certain aerobic and anaerobic organisms may produce a zone of opacity around their colonies when grown in serum-agar media. Clearly this non-specific reaction may lead to erroneous interpretation, especially as a number of strains of *C. diphtheriae* produce concentric rings irrespective of whether they are toxicogenic or not. The methods described below were devised to overcome these difficulties and to place in the hands of laboratory workers a technique which it is hoped will find a useful routine application.

The New Technique

In working out this technique three principles have had to be considered: to obtain maximal and rapid toxin

production: to produce an antitoxin gradient in the medium so as to give a reaction with varying toxin concentrations; and to provide non-specific serum constituents in sufficient quantity to make the flocculation reaction easily visible. The nutritional and gaseous requirements for rapid toxin production in most toxicogenic organisms are well known. In the case of *C. diphtheriae* a modified Pope's medium was found suitable, whereas for staphylococci a slight modification of Walbum's medium proved satisfactory. Inoculation in the form of a wide streak will yield *pari passu* with increased bulk of growth far more toxin than a single colony. The minimum length of incubation can be determined only by experiment: it is the shortest time which will reveal all virulent strains as toxicogenic.

The required antitoxin gradient can be achieved by the simple method of placing on the surface of the medium a strip of filter paper moistened with commercial antitoxin in suitable dilution. The concentration of antitoxin at any point on the plate is determined by the laws of diffusion

Fig. 1.—Completed test with corynebacteria. Strain 1=positive control; strain 2=non-toxicogenic; strain 3=toxicogenic.

governing this complex system, and varies from a maximum (corresponding to the concentration of the antitoxin used) to a minimum in the part of the plate most remote from the strip. In order to provide non-specific serum constituents in sufficient quantity to make flocculation reaction easily visible it has been found better to incorporate 20% normal horse serum in the medium rather than to rely on the constituents of the crude antitoxic serum, which diffuse at a different rate from the immune globulins.

If the organism to be tested is inoculated in the form of a wide line at right angles to the filter paper the toxin produced by the organism will diffuse out in descending concentrations, just as the antitoxin diffuses from the filter strip. In these circumstances the points of optimum proportions for toxin-antitoxin reaction fall on a continuous line, and the flocculation which occurs along this line provides striking graphic representation of the law of optimal ratios. On each side of the inoculum a white line develops at an angle, so that a toxicogenic strain becomes virtually marked with an arrow-head (Fig. 1).

The principles outlined above have been adapted for the examination of *C. diphtheriae* and staphylococci, and the special procedures for these organisms are detailed below; the technique, however, should be capable of adaptation for any toxicogenic organism—aerobic or anaerobic. Furthermore, it is possible that substances diffusing from bacterial cultures, but not commonly regarded as exotoxins, can also be used for purposes of recognition if suitable antisera are employed.

Method for Examination of *C. diphtheriae*

Materials.—The medium is prepared by dissolving 4 g. of protose-peptone ("difco"), 0.6 g. of maltose, and 0.14 ml. of lactic acid (B.P.) in distilled water. The volume is made up to 100 ml. and the pH adjusted to 7.8. A 3% solution of agar in 1% sodium chloride is cleared by filtration through paper pulp and its reaction is adjusted to pH 7.8. It is further clarified by treatment with charcoal, and again filtered through pulp. Equal parts of the peptone and agar solutions are mixed together and distributed in 10-ml. quantities, which are sterilized by steaming for 30 minutes on three successive days. The antitoxin used is refined diphtheria antitoxin globulins (Burroughs Wellcome and Co.) diluted with physiological saline to a concentration of 1,000 units per ml. The filter-paper strips are prepared from sheets of good quality filter paper (Postlip 633 was used). This is cut into strips measuring 6 by 1.5 cm. and these are placed in a plugged test-tube and sterilized in the hot-air oven.

Procedure.—Plates are prepared by melting 10 ml. of the medium, adding 2 ml. of sterile normal horse serum, and pouring into 3½-in. (8.75-cm.) Petri dishes. A sterile filter-paper strip is now dipped in diluted antitoxin, and after excess antitoxin has drained off it is laid across the surface of the freshly poured plate and allowed to sink into the medium while it is still fluid. The plate is then dried thoroughly in the incubator and should be used the same day. The organisms to be tested are inoculated by a loop in the form of a wide streak right across the plate. Three or four such streaks are readily accommodated on a single plate, and each set should include a known toxiceogenic strain as a positive control. The plate is incubated and examined after 24 and 48 hours.

Results

A positive reaction is denoted by the appearance of fine white lines forming an arrow-head within 1/2 in. (1.25 cm.) of the filter paper and pointing towards it. It makes its appear-

ance after about 22 hours' incubation in some strains, and in its earliest stages has to be sought with a hand lens. It is best seen by reflected light against a dark background. After 48 hours the arrow-head is easily visible to the unaided eye by transmitted light. A completed test is shown in Fig. 1.

If the plates are left at room temperature the density of the lines gradually increases, but secondary lines may develop which possibly represent the interaction of bacterial substances diffusing out from the growth with antibodies corresponding to them present in the serum. The presence of such antibodies may be assumed from the fact that the material used for the immunization of animals contains numerous substances in addition to the toxin itself. These secondary lines may appear with both toxicogenic and non-toxicogenic strains, and with the latter might lead to difficulty in interpretation. If, however, the final readings are made directly after 48 hours' incubation no confusion arises from this cause, as several days at room temperature are required to bring out the secondary lines. Even then they are very soft, and their detection usually requires the aid of a lens.

The plate shown in Fig. 2 demonstrates that the opacity produced in serum media by certain strains of corynebacteria is independent of toxin production. The strain on the left shows opacity and the arrow-head denoting toxin production; the strain in the middle shows the opacity but no toxin-antitoxin line. The right-hand strain (the positive control) shows the arrow-head only. On standing at room temperature these opacities lose homogeneity and become distributed in the form of concentric denser and clearer areas resembling Liesegang rings. Clearly the development of rings cannot be accepted as proof that a toxin-antitoxin reaction is taking place.

The accompanying Table shows the results obtained with this test on 20 strains of corynebacteria, all but one of which (No. 2) gave typical morphological and cultural characters of *C. diphtheriae*. Of the 13 virulent strains eight showed a positive reaction in 24 hours, while with the remaining five the reaction became positive only after 48 hours' incubation. None of the seven avirulent strains showed a positive reaction after 48 hours.

Method for Examination of Staphylococci

With the staphylococci ability to form a toxin is clearly not the sole factor determining virulence, since these organisms invade the body. Nevertheless a simple procedure for the detection of toxicogenicity might well prove to be of value for both clinical and experimental purposes. The staphylococcal toxin-antitoxin reaction can be recognized in an agar plate was shown by an accidental observation made in 1944 on a routine plate (Fig. 3). A method similar to the one described for the diphtheria bacilli was devised and tried in a small number of cases.

Materials.—The medium used consists of heart-infusion broth (difco) to which 0.2% potassium acid phosphate (KH₂PO₄) and

0.03% magnesium sulphate ($MgSO_4$) are added. Both salts are used crystalline. The pH is adjusted to 6.8, and the broth, which is somewhat yellow, is clarified with charcoal. Agar is now added to a concentration of 1.5% and the medium filtered and clarified in the usual way. It is distributed in 10-ml. quanti-

to 32 strains of staphylococci. Of these nine were obtained from the fingers or were obviously contaminants on plates, and only one—an *aureus* strain obtained from the hand of a laboratory worker—gave a positive result in 48 hours. Ten strains, being obtained in pure culture from typical staphylococcal lesions, were assumed to be pathogenic, and nine of them gave positive results in 48 hours. The remaining 13 strains were obtained in the course of routine work from various sites and three of them failed to give a positive reaction.

Discussion

The application of these methods has not yet reached a stage at which detailed discussion of the results would be profitable, and the object of this paper is to present the new *in vitro* technique and to indicate directions along which development is possible.

Clear-cut results have been obtained with a small series of *C. diphtheriae* strains, and they show that there is a high correlation between *in-vitro* toxicogenicity as detected by this test and the so-called "virulence" as detected by the usual guinea-pig test. It is a generally accepted fact that pathogenicity is not a good basis for bacteriological classification, as virulence is not a permanent intrinsic property of a given species. It is, however, precisely this point which is of paramount interest to the medical bacteriologist: to him a non-virulent strain is not a "true" representative of the species, and is indeed the worst nuisance, since its unimportant character is revealed only after lengthy investigations, involving animal experiments. Animal tests have numerous disadvantages in a routine laboratory, and it is hoped that the *in-vitro* test may well prove of practical value on account of its great simplicity and the relatively short time needed to obtain the result.

Once an organism has been assigned to the *Corynebacterium* group on morphological grounds and grown in pure culture the test can be applied without investigating the biochemical properties of the strain and without classification as regards its type, as the specificity of the reaction with diphtheria antitoxin is axiomatic. Theoretically not every toxicogenic strain need be virulent. If this differentiation really does exist between the *in-vitro* and the animal test a larger series of parallel tests should reveal this. As, however, every virulent strain is by definition toxicogenic, from the utilitarian point of view there is no source of error in the test. Clearly, further work is needed to establish whether or not this test can be relied upon to replace the accepted virulence tests in practice.

The results with the staphylococci are less well defined, but here again there is high correlation between a positive test and clinical pathogenicity. In addition to the possible use of the test in clinical bacteriology the procedure may prove to be of value in investigating the diffusible products of staphylococci. The multiplicity of lines developing with the positive strains suggests the presence of several interacting substances and clearly requires further study.

Without substantial modification the same technique can be used for the identification of the anaerobes by means of their specific toxins. The technique should also be capable of wide application to other groups of organisms by investigating diffusible antigenic substances produced by the culture but not usually regarded as exotoxins.

Summary

The principles of a new technique for the *in-vitro* detection of bacterial toxicogenicity are outlined.

Tests utilizing these principles and adapted for examination of *C. diphtheriae* and staphylococci are described.

FIG. 3.—Routine plate showing staphylococcal toxin-antitoxin reaction. Plate inoculated with patient's strain of *Staph. aureus*. Upper cups contain penicillin solution (1 and 5 units per ml.); lower cups contain pus from patient's abscess—the left shows presence of penicillin and a ring believed to be a toxin-antitoxin reaction.

ties in tubes and sterilized in the autoclave. For antitoxin refined staphylococcal antitoxin globulins (Burroughs Wellcome and Co.) are employed, diluted so as to contain 1,000 units per ml.

Procedure.—This is precisely as in the former method, except that normal horse serum is not incorporated in the medium, as its addition was not found to improve the reaction. Readings are taken with a lens after 48 hours' aerobic incubation. The effect of incubation in an atmosphere of carbon dioxide was not tried.

Results

The lines which form with toxicogenic strains are multiple and are fainter than those formed with *C. diphtheriae*, so that their presence has to be sought with the aid of a hand lens. A typical plate is shown in Fig. 4. The test has been applied

FIG. 4.—Completed test with staphylococci. All strains show multiple line formation.

Results with a small number of strains show a high correlation with the results of animal virulence tests in the case of *C. diphtheriae* and with clinical pathogenicity in the case of staphylococci.

The possibilities of wider application of the technique for both clinical and experimental purposes are discussed.

I wish to express my thanks to Dr. Theo. Crawford for his help in the preparation of this paper, and to Dr. J. E. McCartney for kindly providing some of the *C. diphtheriae* strains used and for carrying out the virulence tests. I wish also to thank Mr. T. W. Shaw for technical help.

SPERANSKY'S METHOD OF SPINAL PUMPING IN RHEUMATOID ARTHRITIS

A REVIEW OF FOUR CASES

BY

OSWALD SAVAGE, O.B.E., M.R.C.P.

Assistant Physician, B.R.C.S. Rheumatism Clinic, Peto Place;
 Chief Assistant, Rheumatism Department,
 West London Hospital

(From the Rheumatism Department, West London Hospital)

The recent interest shown in Speransky's method of treating rheumatic cases by means of "spinal pumping" make it worth while to report four cases of rheumatoid arthritis which were treated in this way and followed up for a year. Speransky (1935) gave reasons for his belief that the nervous system played an important part in acute and chronic disease. Ponomareff and Tchechkoff (1927) and Jowelew (1930) studied the passage of antibodies through the blood-stream barrier of the spinal cord in rabies and attempted by spinal pumping to break it down.

The operation, which consists in withdrawing and replacing 20 ml. of spinal fluid slowly twenty times, takes about an hour. The spinal fluid in each of our cases was sterile, and laboratory tests showed no abnormality. The only reactions were vomiting in one case, and a transient rise of temperature in another. Spinal pumping is not an easy procedure to carry out in cases of active rheumatoid arthritis, for the patients find it difficult and painful to get into a suitable position for lumbar puncture.

Speransky claimed good results with this treatment in malaria and typhus, and also in the rheumatic diseases. He treated 100 cases of "polyarthritis" by spinal pumping, giving intensive salicylate therapy before and after, and found that of 52 patients with their first attack of rheumatic fever 70% appeared to show complete recovery. Of 15 cases of chronic arthritis, 4 were reported recovered, 9 improved, and 2 unchanged.

Later the Gullman brothers (1946) issued an account of their trials of spinal pumping, and interest was reawakened in the subject. They reported good results in 36 cases of subacute rheumatism following rheumatic fever and in 22 cases of chronic arthritis which had failed to respond to gold and physiotherapy. In 12 of these chronic cases there was great improvement, with a return of the sedimentation rate to normal in two weeks; in the remaining 10 the condition was unchanged. After the spinal pumping they noted a rise in skin temperature, and visible dilatation of the peripheral skin capillaries which lasted for days. No unpleasant side-effects were encountered, such as severe headache and vomiting, and, in one

case with hypertension, death due to multiple cerebral haemorrhages followed the third pumping. After publication of that report it was decided to try spinal pumping in the following cases of rheumatoid arthritis which had failed to respond to more rational methods.

Case 1

A hospital sister aged 54 had had arthritis for a year. It had spread rapidly to her hands, wrists, feet, knees, and elbows in the last six months. She was admitted on June 18, 1946, with clinical rheumatoid arthritis—afebrile. Radiographs revealed generalized decalcification with loss of joint space. A blood examination showed: red cells, 3,850,000; Hb, 70%; white cells, 5,500; differential count normal; W.R. negative; uric acid, 2.6 mg. per 100 ml.; sedimentation rate, 25 mm. in one hour (Westergren), which rose to 40 mm. in the next five weeks. Treatment with "myocrysin," salicylates, 1,000,000 units of penicillin, complete bed-rest, and plasters brought no improvement, and as she was rapidly becoming crippled it was decided to carry out spinal pumping. This was performed on Aug. 1 after a preliminary course of 10 g. of salicylate in 24 hours. The C.S.F. pressure at the onset was 180 mm., and at the end 70 mm. Salicylate, 10 g., was given during the next 24 hours. Five hours after pumping the patient complained of feeling "burning hot, especially in the forearms and feet," though there was no rise in general or skin temperature and no demonstrable capillary dilatation. This lasted for 12 hours. The joints then improved, and in a month the sedimentation rate had dropped to normal and the patient was up, walking, and free from pain. She proceeded to a convalescent home.

In February, 1947, the B.S.R. was 5 mm. In September, 1947, it was 8 mm., and she was doing light work, typing and playing the organ with some difficulty, and having to take three or four "veganin" tablets a week for pain in her wrists and ankles. There was a moderate degree of deformity and crippling, though it was no worse than in August, 1946. She had had no treatment since October, 1946. Radiographs showed no change from August, 1946.

Case 2

A Polish housewife aged 54 had suffered from intermittent arthritis in the knees, wrist, and hands for 20 years. It had been much worse in the last six years, since she had come to England. In spite of physiotherapy and gold injections at the B.R.C.S. Clinic, Peto Place, her condition had got worse. When admitted on Aug. 18, 1947, she was crippled with rheumatoid arthritis and had been unable to walk for two months. The

FIG. 1.—The blood sedimentation curve in Case 2.

B.S.R. was 110 mm. in one hour (Westergren); blood uric acid 2.5 mg. per 100 ml.; Hb, 83%; white cells, 7,200.

Spinal pumping was carried out on Sept. 6. Salicylate was not given before or after. The C.S.F. pressure was 180 mm. After 10 withdrawals the pressure dropped to 35 mm. and the pumping was stopped. A reaction similar to that of Case 1 came on six hours afterwards, with a feeling of heat in forearms and legs lasting 12 hours. She had a general fever of 100° F. (37.8° C.), but no demonstrable capillary dilatation. During the next week the joint condition improved, and four weeks later she was discharged. Fig. 1 shows the course of

her B.S.R. She has been treated as an out-patient with myocrisin. The patient was readmitted on July 7, 1947, for active rheumatoid arthritis. The B.S.R. was 55 mm. Further spinal pumping was tentatively suggested, but was refused. She still has an active rheumatoid arthritis, but is able to get about and do some housework.

Case 3

A housewife aged 48 was admitted on Aug. 30, 1946, for clinically active rheumatoid arthritis with effusions in the knee-joints. The history was of rapid onset of arthritis involving the hands, wrists, elbows, and knees two months before. The temperature was 99° F. (37.2° C.), and the B.S.R. 45 mm. Radiographs of the hands revealed general decalcification and reduction in joint spaces. Blood examination showed: uric acid, 2.8 mg. per 100 ml.; red cells, 4,350,000; Hb, 64%; white cells, 10,000. This patient refused gold treatment and requested to have spinal pumping, as Case 2, whom she knew, had improved so much.

Spinal pumping was carried out on Sept. 19, 1946, 10 g. of salicylate being given before and after. The C.S.F. pressure at the beginning was 180 mm. and at the end 160 mm. This patient had the same feeling of warmth at the periphery as Case 1, but with no demonstrable signs. Forty-eight hours later the joints were much improved, and a week later she had full movement and no pain, but the B.S.R. had risen to 85 mm. Twenty-five days later she was discharged, the B.S.R. being

FIG. 2.—The blood sedimentation curve in Case 3.

45 mm. Fig. 2 shows her B.S.R. curve. She attended as an out-patient and had myocrisin till March, 1947, when the B.S.R. was 11 mm. On Oct. 10, 1947, she was doing full housework and had no pain or limitation of movement; the B.S.R. was 12 mm.

Case 4

An engineer aged 40 had for eight months been feeling ill and losing weight, with pain and swelling which started in the left great-toe joint and spread rapidly to the feet, right hip, knees, and right wrist. He had been treated elsewhere with injections of a local analgesic and manipulation of the right hip, but had steadily got worse. On March 21, 1946, he was pale and emaciated, with commencing ulnar deviation of the hands, limited movements of the hands and feet, and much muscle spasm. He had synovitis of the left knee and his ankles were swollen. The B.S.R. was 70/100 in one hour (Westergren); Hb, 73%; white cells, 11,600; blood uric acid, 2.6 mg. per 100 ml.

He was admitted to hospital, and for 10 weeks was treated with rest, plasters, gold, and blood transfusion. There was considerable improvement, but the rheumatoid arthritis was still active and the B.S.R. was 65 mm. As he was very anxious to get back to work he was offered spinal pumping in the hope that it would hasten the improvement. This was carried out on Oct. 1, 1946, after 10 g. of sodium salicylate had been given. Pressure at the beginning was 140 mm. and at the end 210 mm.

The patient was a trained scientist, and he kindly noted his reactions for us:—At operation: "No discomfort and no back-ache when it was over." First day: "Woke with violent headache and nausea and felt hot all over. Throughout the day experienced quite involuntary movements of the joints—i.e., sudden jerk of knee-joints or ankles or shoulders." Second day: "Still hot and having involuntary joint movements." Third day: "All reaction over." On discharge from hospital two weeks later: "On the whole no marked

change." Some joints were less painful, others more so. There was no rise in temperature after the pumping and the B.S.R. was unchanged.

FIG. 3.—The blood sedimentation curve in Case 4.

The patient continued to have gold as an out-patient and steadily improved. He has gained 1 st. (6.35 kg.), is back at work, and is fit enough to swim, though he still has pain in one shoulder, elbow, and wrist. Fig. 3 shows his B.S.R. curve.

Comment

It may be of some interest to include the views of the patients themselves as to the efficacy of this treatment.

Case 1 slowly became quiescent after the pumping and has remained so. We were quite impressed with her improvement at the time, though it was not so dramatic as other writers had recorded, and the disease has remained quiescent. A year later the patient "does not believe the pumping had anything to do with it."

Case 2 still has very active rheumatoid arthritis. When readmitted to hospital a year later a further pumping was tentatively suggested, but she refused.

Case 3 requested this treatment and is convinced that it cured her. Certainly the disease is still inactive a year later, and the small amount of myocrisin (0.14 g.) which she had afterwards is not alone likely to have had this effect.

Case 4, whom we consider the most accurate observer, recorded "no marked change."

Discussion

No conclusions regarding the value of this treatment can be drawn from such a small number of cases. We saw no sign of dramatic improvement such as a return of the B.S.R. to normal in two weeks as recorded by the Gillmans in their 12 cases of chronic arthritis. All our patients described the same type of reaction as that noted by the Gillmans—that is, a subjective feeling of heat coming on a few hours after the operation and lasting up to 48 hours. In three it was most pronounced at the periphery. We were, however, unable to observe any objective sign of this, such as a rise in skin temperature or peripheral or orbital dilatation of vessels. Rheumatoid arthritis is an extremely difficult disease in which to assess the value of any particular treatment, because its natural history shows periods of remission and relapse.

All the cases were under the care of Dr. W. S. C. Copeman, and it is a pleasure to record my indebtedness to him for encouragement in carrying out the treatment and in writing this report.

DIVERTICULITIS PRESENTING AS EMPHYSEMATOUS CELLULITIS OF LEG

CLINICAL REPORT ON TWO CASES

BY

R. L. G. DAWSON, F.R.C.S.*Assistant Surgical Registrar*

AND

R. H. HARDY, B.M., B.Ch.*House-Surgeon**University College Hospital, London*

A case of diverticulitis of the large intestine which presented as an emphysematous cellulitis spreading down the leg from the left groin is considered of sufficient general interest to merit recording. This occurred in a patient under observation for another condition. A similar case which occurred in the hospital in 1908 has been recalled by a senior member of the staff and is also recorded.

Case History

Mrs. C., aged 73, was admitted on Nov. 30, 1946; for excision of a rapidly growing tumour of the skin of the lumbar region. This was removed by wide excision down to the lumbar fascia, the exposed area being left to heal by granulation. The tumour was found on section to be a benign neurofibroma. She had never had any gastro-intestinal symptoms. On Jan. 27, 1947, while awaiting skin-grafting, she developed an attack of pyrexia,

Tracing of antero-posterior radiograph of barium enema, showing rectum full of barium. Abscess and fistula leading from it. X marks the site of obstruction.

the temperature reaching 102° F. (38.9° C.) on Jan. 31. The pyrexia was associated with backache, diarrhoea, vomiting, and some difficulty of micturition. By Feb. 4 the temperature had subsided, and thereafter remained subnormal. On Feb. 6 the patient developed a painful, tender, deep-red swelling in the left groin. This was considered to be an inguinal abscess, and as such was being treated expectantly with local heat until it should fluctuate. This did not, however, happen. The swelling developed into a rapidly spreading cellulitis which soon involved the left lumbar region, spread laterally almost to the midline, and anteriorly almost to the midline, and for a few inches down the anterior aspect of the

thigh. The swollen area was crepitant to palpation and covered with bullae containing blood-stained fluid.

On Feb. 8 the swelling was incised under general anaesthesia, with liberation of large quantities of very foul-smelling, frothing sanious pus from the deeper subcutaneous layers. In the course of wide excision of the affected area a track was found leading over the brim of the pelvis, just lateral to the mid-inguinal point, into the pelvic retroperitoneal tissues. A provisional diagnosis of gas-gangrene was made, and, although no clostridia were seen in a direct smear, appropriate specific treatment was started at once. Culture ultimately showed the infection to be due to *Bact. coli* and *Str. faecalis*. No further pyrexia occurred, and the local condition responded rapidly to intensive local and general treatment.

On Feb. 13 the previously defined track became the site of a faecal fistula which persisted intermittently until death. Discharge of pus from the area was controlled with sulphasuxidine and later with phthalyl-sulphathiazole supplemented with riboflavin and nicotinic acid. By March 1 the patient's general condition had improved sufficiently to permit examination by barium enema, on which the radiologist reported as follows: "Barium passed normally through the rectum into the first part of the sigmoid. There was an irregular filling defect past which the barium would not flow. It outlined an irregular fistulous track running down towards the left groin. The film taken after evacuation is suggestive of the presence of diverticula of the colon." The films are unfortunately not good enough for publication, but a tracing from one antero-posterior view is shown in the accompanying illustration. On March 14 a sigmoidoscope was passed to 20 cm. and showed no abnormality.

Owing to the persistence of the fistula and to recurrent attacks of subacute intestinal obstruction a colostomy was considered necessary, and laparotomy was performed on April 11. A large mass was found in the region of the sigmoid attached to the side wall of the pelvis, with several loops of small intestine adherent to it. The gut proximal to these adhesions was dilated and hypertrophied. In attempting to free them from the mass a small abscess was inadvertently opened. Transverse colostomy was performed through a transrectal incision, the abscess being drained through the midline laparotomy wound. The patient died two days later from general peritonitis.

The post-mortem findings were as follows: "The pelvis was almost entirely occupied by a large mass involving the sigmoid colon. Connected with the lumen of the gut were numerous diverticula, which were infected and haemorrhagic. The gut wall in this region was extremely thick, with mucoid or gelatinous deposit producing great deformity of the lumen. About 6 in. (15 cm.) of gut was thus involved, and there was no evidence of carcinoma."

The 1908 Case

In spite of the lapse of time since its occurrence, this case is recorded because of the rarity of the condition and its close similarity to the recent case. The 1908 case was referred to by Barrington and Gardham (1932), but was not fully reported.

Mr. S., a hotel-keeper aged 52, was admitted under Mr. Barker in a moribund condition on June 3, 1908. He came in at 1 a.m., with a diagnosis of intestinal obstruction and emphysematous gangrene of the leg. The patient's doctor supplied a history of moderately severe pain on the left side of the abdomen for two days and reported that "a lump could be felt here, but that nothing could be felt by rectum." The pain was first in the hypochondrium but later in the iliac region. The patient had been unwell for five days. He had had diarrhoea and vomiting but no constipation; he had also suffered greatly from eructations for some time.

On admission he was pale and rather cyanosed. Respiration was 42 a minute. The pulse was rapid and could hardly be felt at the wrist, and the heart sounds were scarcely audible. The abdomen was distended, but the patient said that he was always stout; it was not rigid or tender, and was resonant all over except for some slight impairment in the left flank. The left leg was blotchy and cyanosed in colour, cooler than the right, and the sense of touch with the finger was absent all over it. The pulse in the left dorsalis pedis and femoral arteries could

not be felt, but on the right side they were distinctly palpable. The patient complained of great pain in the left leg, which was partly relieved by elevating the leg and applying leeches.

In the left thigh there was a superficial crepitant sensation resembling surgical emphysema. This was limited sharply above by Poupart's ligament, but, below, the margin was not definite, extending down to the knee in some places. The patient was very restless; the dyspnoea gradually increased, and he died at 4.15 a.m.

The post-mortem report mentions the dark-red colour of the lesion, the large bullae projecting from the surface, and the involvement of the left side of the scrotum. Culture from the leg post-mortem gave several organisms, chiefly *Bact. coli*. *Bact. aerogenes capsulatus* was not present. "Thrombosis of the veins of the leg had occurred; the muscles of the thigh—iliacus and psoas—were involved in the gaseous necrosis. The intercostal muscles were also involved. The whole of the retroperitoneal tissues on the left side of the abdomen were full of a liquid brownish pus. There was a thick adhesion between the descending colon and the retroperitoneal tissues, and in this there was a recent perforation. In the large intestine there were numerous small pockets of mucous membrane bulging into the peritoneal cavity. There was no obstruction of the large intestine."

A diagnosis of "sacculization of the large gut, stercoral ulceration, perforation, and emphysematous gangrene of the leg" was made.

Summary

Two cases of diverticulitis presenting as emphysematous cellulitis of the leg are described, one in a woman and one in a man. Points of similarity between the cases are set out. In the first case the patient developed the clinical manifestation of the underlying disease while in hospital for another reason; she ultimately died of peritonitis following a therapeutic colostomy, in spite of prolonged and intensive general and local treatment. The second patient was admitted in a moribund condition and died of the immediate and very far advanced sepsis.

Our grateful thanks are due to Mr. A. J. Gardham for encouragement and permission to publish the first case, to Mr. F. J. F. Barrington for references to the second, and to all who have in any way assisted in the preparation of this account.

RECURRENT RENAL LITHIASIS

BY

A. DICKSON WRIGHT, M.S., F.R.C.S.

Surgeon to Out-patients, St. Mary's Hospital

The condition of recurrent renal calculi associated with infection has been a urological bugbear for a very long time, and the apparently satisfactory outcome of the following extreme case seems to render it worthy of record.

Case History

The first operation was done by the late Girling Ball in 1936, when the patient was aged 24. An oval stone was removed from the pelvis of the left kidney, and infection with *Bacterium coli* was present at this time.

The subsequent ten operations were performed by me during the next ten years, and are summarized diagrammatically. Never during this time was she free from gross pyuria, and *Streptococcus faecalis*, *Bacillus proteus*, staphylococci, and *Pseudomonas pyocyanea* found company with the *Bact. coli* of the first occasion. The patient suffered much misery from recurrent attacks of renal colic associated with fever together with renal aching nearly all of the time. Naturally every method was used to try to overcome the infection—ketogenic diet, mandelic acid, sulphonamides, penicillin, N.A.B., etc. The stones were always a mixture of phosphates and seemed to be unaffected by reducing calcium intake and drinking large amounts of distilled water. Calcium metabolism was carefully checked and found normal.

After some of the later operations small tubes were left in the infected calices and irrigated continuously for two weeks

with various solutions, G1, G2, associated with sulphonamide solutions and penicillin. On two occasions a ureteric catheter was left in the ureter and the irrigating was done through this with a nephrostomy tube for outflow. All these methods were in vain, the infection in every case reappearing before the patient had left the hospital, and the stones rapidly forming soon after.

With the last two operations streptomycin was used systemically for two days before the operation, and the urine for the

first time for ten years became sterile. Four stones were removed, and radiographs taken during the operation with a small oral film inserted into the depths of the wound visualized no stones. A radiograph on the second post-operative day showed two small calculi still present, so the wound was reopened and these were removed by the device of drawing half a small dental wool roll on a silk thread from the pelvis through the diseased inferior calices. Streptomycin was used for seven days in all—1,000,000 units daily in three-hourly doses—and the diseased calices were also irrigated with streptomycin solution—1,000 units per ml.—for seven days after the operation.

Six months later the urine is clear of infection and the kidney of stone, and the patient is free from symptoms.

Medical Memoranda

Central Placenta Praevia with Premature Rupture of Membranes

The following case is of sufficient practical importance to merit publication.

CASE HISTORY

Mrs. A., aged 45 and separated from her husband, had had three normal pregnancies before the age of 30; thereafter she suffered from severe menorrhagia, which was relieved by curettage and removal of a fibroid polyp; hysterectomy had been advised on account of fibroids, but conception temporarily removed her symptoms. Her fourth pregnancy was illegitimate and unwanted, and she was due for confinement on May 19, 1947. Irregular bleeding began in the early months, and there was a severe haemorrhage at 28 weeks; after three weeks in bed there were three more attacks in a fortnight, and she was admitted on April 9 in her 34th week, following her fifth haemorrhage.

On examination she was seen to be somewhat anaemic, the haemoglobin amounting to 62%. The uterus was not contracting and there was no vaginal loss. A foetus equivalent in size to 34 weeks' pregnancy was presenting by vertex (not engaged) and with regular heart sounds. There was no oedema, albuminuria, or rise of blood pressure. Speculum examination of the cervix disclosed no local cause for bleeding.

A provisional diagnosis of placenta praevia was made; a conservative regime was adopted in view of prematurity and the patient confined to bed. Two days later, however, the membranes ruptured, with copious loss of clear liquor, and 48 hours later contractions started. These increased steadily for 20 hours, during which period there was no bleeding, the presenting part remained high, and no pelvic examination was made. Brisk haemorrhage eventually ensued, and preparations were made for vaginal examination under an anaesthetic; but caesarean section was not seriously contemplated, since the foetus was six weeks premature, the membranes three days ruptured, and the placenta presumed to be well away from the os.

Delivery.—Under thiopentone anaesthesia examination showed a soft cervix rather less than half dilated and completely covered by thick placental tissue; the presenting part was high, but was easily palpated through the anterior fornix. Two fingers were passed up between placenta and anterior lip of cervix to re-rupture the membranes and fasten two pairs of Willett forceps on to the foetal scalp; the placenta was pushed back, the head drawn down, and 1 lb. (0.45 kg.) traction weight secured to the forceps handles. Surprisingly little haemorrhage attended these manoeuvres, but there was sufficient loss to warrant blood transfusion. Four hours later a stillborn child weighing 4 lb. 13 oz. (2.18 kg.) was delivered. The placenta failed to separate, and after 1½ hours of slight bleeding the patient was again anaesthetized. An attempt at expression was unavailing, and manual removal was undertaken. The placenta was found on the posterior wall, the upper part separating easily; but inferiorly it was densely adherent to the lower segment and cervix, from which it could be clawed off only with great difficulty and much loss of blood. The patient's condition became critical; the lower uterine segment was packed with gauze, and a total of 5 pints (2.84 litres) of blood was given before satisfactory recovery ensued.

DISCUSSION

The pathology of the condition was undoubtedly an imperfect placental development in the lower part of the uterus (partial accretal, with morbid adhesion more or less all round the internal os). Thus the membranes must have bulged round the anterior placental border to rupture at the least-supported spot, while subsequent dilatation of the cervix was considerably hindered and bleeding relatively slight. The practical importance of the rupture of membranes was to give an unwarranted trust in vaginal delivery and to trust to vaginal delivery. This policy was apparently endorsed by the early freedom from bleeding but hastily condemned by the difficulty and danger of the third stage. The morals that may be drawn are two: ante-partum haemorrhage is a potential caesarean section until the labour has passed through the cervix; and a patient with ante-partum haemorrhage may die of postpartum haemorrhage if delivered vaginally.

A note of thanks is due to Mr. Kenneth MacMillan for his permission to publish this case.

Birmingham Maternity Hospital.

Occupational Dermatitis Occurring in Transplanted Skin

The following case of occupational dermatitis occurring skin graft to a finger may be of interest to casualty surgeons and to dermatologists—to the former as a complication of technique, and to the latter as a factor in the aetiology of occupational dermatitis.

CASE REPORT

The patient, a man aged 38, had been employed for some 20 years as a wet grinder of brake drums and other car components, sustained an injury to the soft tissues of the dorsum of the terminal phalanx of the right ring-finger. Superficially there was no skin, nail, and part of the nail bed, and, more deeply, the tendons of the extensor digitorum longus was divided and the bone lacerated.

At operation in hospital the damaged tissues were repaired, the lost skin made good by the application of a cross-arm flap, the upper extensor aspect of the left forearm; it was noted that the medial and lateral neurovascular structures were intact. Recovery was uneventful, and six weeks after the date of injury the patient returned to his original job without having been subjected experimentally to the exact working conditions of the job, his hands were continuously bathed in a dilute solution (varying 5 to 10%) of washing soda.

Twenty-four hours after starting work a vesicular eruption appeared over the area of the grafted skin, and after attempting to carry on the next shift he reported sick. When examined the condition of the graft was noted to be as follows. A whole skin graft covered the dorsal aspect of the terminal phalanx of the ring-finger. The graft had taken well, and a definite small area delimited its extent. The whole of the skin-graft area showed a erythema, and a few scattered vesicles were seen. The surrounding skin was normal. In addition there were areas of desquamation where vesicles had broken down, showing increased erythema of the underlying tissue layers. The transplanted skin contained follicles, and the openings of these were prominent and distinct. The whole appearance was compatible with a localized occupational dermatitis due to contact with a mild irritant fluid.

Daily treatment with a simple zinc-and-tar lotion and a dressing was immediately instituted, and arrangements were made for the patient to be placed on dry work. The condition cleared after one week, and at the time of writing (some four weeks after the man's return to work) he is on a job under dry conditions but being given a further contact trial.

DISCUSSION

This man had never previously shown any reaction to washing solution, with which he had been continuously in contact for 20 years. It is presumed, therefore, that the irritant factor was the contact between sensitive skin—i.e., from the upper part of the forearm—and the soda solution, which was both a mild irritant and a macerating action. The skin was only six weeks old, and it is probably correct to assume that the blood supply was still inadequate.

The chance of an occupational dermatitis occurring in skin grafts should be borne in mind by surgeons and by medical practitioners when certifying a man as fit to return to his pre-accident job. Industrial medical officers and those in charge of skin clinics should recognize its possibility, and arrange for slow initiation, under supervision, of skin-graft cases in contact with industrial irritants.

The reaction in this case was to dilute alkaline solution, one of the less common skin irritants met with in industry. The distended condition of the hair follicles following contact indicates that in carrying out skin grafts on the hands of machineists casualty surgeons should consider the possibility of taking skin from a less hairy area than the extensor surface of the forearm, thus reducing the risk of infiltration of the follicles with industrial solutions.

Prosser White (*The Dermatogoses*, 4th ed., 1934, p. 10) states that, "apart from the activity of the irritant and the sensitivity of the nervous system, liability to injury depends upon whether the skin is normal in structure and healthy in function." In the case of transplanted skin it is likely that six weeks vascularization is still incomplete, and therefore the powers of recuperation from continued low-grade chemical trauma are less than those of normal skin.

Reviews

ZEST IN OLD AGE

Old Age. Its Compensations and Rewards. By A. L. Vischer. Foreword by Lord Amulree, M.D., F.R.C.P. (Pp. 200; illustrated. 12s. 6d.) London: George Allen and Unwin. 1947.

In the ages of mediaeval Christian faith a "good death" was regarded as the crown of life (not necessarily always of a good life). Nowadays, surely, a healthy old age, with true "ripeness" and preservation of the intellect, has a just claim to be called the crown of an active and well-spent life. Among the many (including some brilliant) medical and philosophical books and essays on old age there is not one, so far as I know, really similar to Dr. Vischer's. Dr. Vischer, who has had exceptional opportunity at Basle for a long and obviously sympathetic study of old persons, gives us the result of his experience and study regarding their physical and psychical peculiarities and infirmities, their mental life, and how best to make them comfortable and happy in the feeling that they are still really playing a useful part in life.

Paediatrics, in spite of considerable opposition, gained recognition as a medical specialty, and now, with the greatly increased proportion of old persons among the public, geriatrics can no longer be denied a place.

When about 20 years of age I once had the privilege of sitting at dinner next to the warm-hearted Sir James Paget. He questioned me on how I spent my holidays, and then he gave me to understand that I was one of those who preferred "change of work" to mere rest or amusing games—I suppose he included the strenuous pursuit of hobbies under "change of work." Change of work doubtless gives a temporary holiday to groups of brain cells—according to the ideas admirably put forward by the late Sir Farquhar Buzzard (1928), quoted with approval by Dr. Vischer (p. 192), and these ideas should be remembered in the management of some of the troubles of late middle age and commencing senescence. Old persons should not be discouraged from making harmless experiments in regard to way of life (including diet), if they find that for a time their vigour and zest in life are thereby increased.

One need scarcely mention that when long periods of continuous physical and mental work become impossible the experience of old persons is often still so useful that they should be recognized as advising, or consulting authorities (not "sleeping partners"). For instance, in our medical profession they might often be made active "consultant diagnosticians" to hospitals and institutions where they were formerly on the regular visiting staff.

The clear wording and admirable translation of Dr. Vischer's book should be specially noted, but not the least feature is its wealth of references to sparkling and appropriate epigrammatic sayings and discussions by previous writers of all kinds bearing on a subject which, perhaps next to love and death, offers itself most readily to literary artists. One piece of advice from early mediaeval Christianity (not included in the book) I once stumbled on—namely, the last two lines of a letter by Paulinus, Bishop of Nola, early in the fifth century (eleventh volume of Migne's *Patrologia, series latina*, column 184): "Vive, precor [another version gives "Vive diu"], sed vive Deo: nam vivere mundo Mortis opus; vera est vivere vita Deo." In the widest possible humanistic spirit I think one should interpret these lines: "Live long the fullest life you can, but live as rightly as you are able to; for to do wrong is death's work: to act rightly is the true life to God."

F. PARKES WEBER.

THE GROWING CHILD

The Child from Five to Ten. By Arnold Gesell, M.D., and Frances L. Ilg, M.D. In collaboration with Louise Bates Ames, Ph.D., and Glenna E. Bullis. (Pp. 475. 18s.) London: Hamish Hamilton. 1947.

In this volume, now in its second edition, the authors discuss the same children as in previous volumes—*The First Five Years of Life*, 1940, and *Infant and Child in the Culture of*

Today, 1943. The study is chiefly longitudinal through seventeen age levels and ten major fields of behaviour, but cross-sections are summarized for the sake of clarity. The study is clinical rather than statistical and experimental, and the behaviour was observed, so far as possible, in the natural setting of school and home. It must be remembered that a child is growing all the time and not at an even rate in all respects, so that a certain cross-section cannot be regarded as normal for any particular child. Nevertheless, a growth gradient and tendency can be discerned as a general pattern of normality.

The age of 5 to 10 lies between the dramatic years of infancy and adolescence and has so far been rather neglected. The present study shows that it has distinctive and important characteristics peculiar to it. Besides marked physical growth there is a surprising mental advancement which, while showing a general progress towards maturity, may not proceed evenly and may even retrogress from time to time. When large numbers are studied the curve of progress smooths out, so that the stage reached by the individual in respect of particular activities and skills can be estimated at any age. Thus we may learn how a particular child needs help or encouragement. To bring up a child successfully the parent and teacher need consideration, a sense of humour or proportion, and a "philosophy of growth"—that is to say, an idea of how the average child develops and what should be looked for at any particular stage. The danger of divided loyalties for the child must be avoided by maintaining a close relationship between parents and teachers.

In the second part of the book the authors describe "behaviour profiles" reached at each successive year from 5 to 10, especially in relation to ten maturity traits and gradients of growth—namely, motor characteristics, personal hygiene, emotional expression, fears and dreams, self and sex, interpersonal relations, play and pastime, school life, ethical sense, philosophic outlook. In the third part they trace the development of these maturity traits through the first ten years of life, though since individual children develop at different rates parents should not be alarmed if theirs has not reached a particular stage at a certain age. From this part of the book, however, it is possible to discover what the average child is likely to be doing at any given stage of development. For example, we can learn how and when a child responds to reason, how his relations with other children change, his interests in sex develop, his conception of God emerges, and so on.

This book will be of great value to parents and teachers, doctors and nurses, and all those concerned with children. For it is interesting to read and useful for reference. Any work done in the Yale clinic of child development, of which Dr. Gesell is the director and Dr. Ilg a prominent member of the staff, is reliable and thorough. A balanced study of childhood is especially important in these days, for "the intrinsic charm and goodness of childhood still constitute the best guarantee of the further perfectibility of mankind."

R. G. GORDON.

POLIOMYELITIS

On the Problem of Poliomyelitis. An Epidemiological Statistical Study. By Bertel S. Son Bertenius. (Pp. 212. No price given.) Lund: Carl Bloms Boktryckeri A.-B. Acta Pathologica et Microbiologica Scandinavica Supplementum LXVIII. 1947.

The author of this publication presents a valuable collection of official statistics and other records of poliomyelitis in many countries, his analysis covering a number of problems. In this review we can only summarize some of his arguments. Large epidemics and an increase in the prevalence of poliomyelitis have been noted only in this century and at first particularly in Sweden, Norway, and the U.S.A. There was a stationary period during the first world war, but in the 1920's the increase was resumed and the population of Iceland, New Zealand, and Australia were affected. Countries with a high incidence of poliomyelitis have low infantile and general mortality rates and a high standard of living. The seasonal incidence has a constant maximum in autumn. Analysis of Swedish and American figures shows that this may be related to climatic conditions, but the reason for it has not yet been elucidated.

The shift in age incidence to older people is contrary to the trend of other infectious diseases in Sweden, which conform to de Rudder's "Law of Age Precession." The shift has occurred to a different extent in different countries and during a high

prevalence in some and a low prevalence in others. Although attack rates in rural districts are often higher than in towns, the reverse has been true in some countries, and Swedish figures show several indications that the attack rate is not inversely related to population density. In Sweden also the case fatality rate is higher in towns than in country districts and highest among people aged 20 to 60 years. These findings lead the author to conclude that immunization by subclinical infections plays no part in determining the incidence of poliomyelitis. He refers to experiments by other workers showing that deficiencies of diet increase the resistance of monkeys and mice to poliomyelitis virus and suggests as a working hypothesis that a predisposition of the individual human being, probably produced by social factors, is a necessary antecedent to acquiring poliomyelitis.

A. M. McFARLAN.

DIGESTIVE TRACT

An Introduction to Gastro-Enterology. A Clinical Study of the Structure and Functions of the Human Alimentary Tube. By James Dunlop Lickley, M.D. (Pp. 143; 21 illustrations. 8s. 6d.) Bristol: John Wright and Sons, Ltd. 1947.

The author's aim is to present a simplified account of the structure and functions of the gastro-intestinal tract which senior students or recently qualified practitioners may use as an introduction to the study of digestive disorders. He first carefully describes the salient features of the anatomy of the intestines. He then gives a chapter on physiology, though, as he says, this is simplified by the selection of certain details for description and the omission of many others. The author then proceeds to describe and elaborate his main thesis, which is that the signs and symptoms of disease of the digestive tract are mainly produced by the actions of the defence mechanisms by which the intestines deal with abnormal situations. Such a conception takes us from the realm of facts to that of hypothesis. For instance, he considers that the increased resting juice found in pyloric stenosis is necessary "to fill the dilated stomach and so enable the impaired gastric muscles to adjust their grip on the stomach content."

It is, however, by his account of the practical clinical applications of his theory that the author is likely to lead the senior student furthest astray. He classifies diseases of the stomach into acute or chronic, generalized or circumscribed mucositis, myositis, or serositis. Such a division is surely an oversimplification, and he is wise not to keep too closely to this nomenclature. Nevertheless, he succeeds in describing and explaining the pathogenesis of the symptoms of peptic ulcer (chronic circumscribed mucositis) in a very few pages.

The author attempts too much and achieves too little. As a manual of gastro-enterology his book contains too little fact and too much theory; as an exposition of the author's particular thesis it suffers from being too simplified and from an absence of verifiable evidence to support an original conception.

CHRISTOPHER HARDWICK.

FAR AND WIDE

Nothing New Under the Sun. By J. P. Lockhart-Mummery, M.A., F.R.C.S. Illustrations by William Wood. (Pp. 178. 12s. 6d.) London: Andrew Melrose, Ltd. 1947.

Mr. Lockhart-Mummery has drawn on his experience, his travels, and his reading, scientific and otherwise, to produce this attractive little book of essays, which are linked by having in common a scientific or historical background. A random selection from the titles—"Fighting Fish of Siam," "How was Man Evolved?", "Why do Dogs like Bones?", "Hormones," "Quacks and Charlatans," "D.D.T.," "What was the Biggest Fertilizer?" gives some indication of the range he covers. The author has an attractive eager style that takes the reader with him in his enthusiasms. He is at his best when considering historical subjects like "The Good Old Days," least satisfactory as an exponent of evolution. The proof reader has made a few mistakes, such as automatically for anatomically on p. 13, and Cheselden for Choselden on p. 124. The book is generally readable. It is attractively produced, and the illustrations by William Wood are a delight to look at.

HELEAGE OGILVIE.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received.]

Méthodes Statistiques en Médecine et en Biologie. By E. Morice et al. (Pp. 177. 480 francs.) Paris: Masson and Cie. 1947.

Textbook of statistics for medical workers.

Die Prophylaxe des Verbrechen. By Heinrich Meng et al. (Pp. 568. 34 Swiss francs.) Basle: Benno Schwabe and Co. 1948.

A study of the aetiology and prevention of crime.

Psychotherapy in Child Guidance. By Gordon Hamilton. (Pp. 340. 22s.) London: Geoffrey Cumberlege. 1947.

A study of the social worker's role in psychotherapy.

Let's Talk About Your Baby. By H. Kent Tenney, Jr., M.D., F.A.A.P. 3rd ed. (Pp. 115. 8s. 6d.) London: Geoffrey Cumberlege. 1947.

Medical advice in plain language for mothers.

Traité de Médecine. Vol. 1. Edited by Prof. A. Lemierre et al. (Pp. 1,096. 2,200 francs.) Paris: Masson and Cie. 1948.

Textbook of medicine: this volume is first part on infectious diseases.

Traité de Médecine. Vol. V. Edited by Prof. A. Lemierre et al. (Pp. 1,163. No price.) Paris: Masson and Cie. 1948.

Textbook of medicine: respiratory diseases.

Guide to Marriage. By Leslie J. Tizard. (Pp. 173. 7s. 6d.) London: George Allen and Unwin. 1948.

A manual for the layman.

Doctors, Drugs and Steel. By Edward Podolsky, M.D. (Pp. 382. 16s.) London: Medical Publications Limited. 1947.

Some recent medical discoveries described for the layman.

Lehrbuch der Inneren Sekretion. By F. Verzar. (Pp. 609. 52 Swiss francs.) Liestal: Verlag Ars Medici Lüdlin AG. 1948.

A textbook of endocrinology.

Women and Men. By Amram Scheinfeld. (Pp. 394. 15s.) London: Chatto and Windus. 1947.

An account of sex differences for the layman.

Fatigue and Impairment in Man. By S. Howard Bartley, Ph.D., and Eloise Chute, M.A. (Pp. 429. \$5.50.) New York and London: McGraw-Hill Book Company, Inc. 1947.

An investigation into the bodily and mental aspects of fatigue.

Practical Psychiatry and Mental Hygiene. By Samuel W. Hartwell, M.D. (Pp. 438. \$3.75.) New York and London: McGraw-Hill Book Company, Inc. 1947.

A textbook for the student of psychiatry.

Local Government. By Sir Arthur MacNally, K.C.B. (Pp. 218. 4s. 6d.) London: Methuen. 1948.

A general account of local government in Britain.

Introduction to Carbohydrate Biochemistry. By D. J. Ball, B.Sc., M.A., Ph.D., F.R.I.C. 2nd ed. (Pp. 107. 6s.) London: University Tutorial Press. 1948.

Intended primarily for students of biochemistry.

Endocrine Therapy in General Practice. By E. L. Sevringhaus, M.D., F.A.C.P. 6th ed. (Pp. 264. No price.) London: H. K. Lewis. 1948.

A practical introduction to endocrinology.

A Century of Medical Service. By B. Darwin. (Pp. 47. No price.) Swindon: Great Western Railway Medical Fund Society. 1947.

A history of the G.W.R. Medical Fund Society.

The Oculomotor Muscles. By R. G. Scobee, B.A., M.D. (Pp. 359. 40s.) London: Henry Kimpton. 1947.

An approach to the diagnosis of dysfunction of the external muscles of the eye.

SATURDAY MARCH 13 1948

THE INDEPENDENCE OF MEDICINE

A Special Representative Meeting will be held next week so that the Representative Body may consider the results of the plebiscite and the consequent policy to be adopted. The Council of the B.M.A. at its meeting on Feb. 18 passed a Resolution to be put before the Special Representative Meeting. It is as follows:

That the Representative Body, reaffirming the whole-hearted desire of the medical profession for a comprehensive health service available to everyone, urges that in the public interest such changes should be made in the Acts of 1946 and 1947 as are necessary to maintain the integrity of medicine and to prevent doctors being turned into State servants, with harmful consequences to patient and doctor alike. The Representative Body therefore expresses the hope that the Government will make it possible for the profession to co-operate by making such changes, and states its view that it is not in the best interests of the public or of medicine for members of the profession to enter the Service until such changes are made.

At its last meeting held before the issue of the plebiscite forms the Representative Body discussed the problems before it in a thoughtful, quiet, but determined manner, thereby showing its sense of responsibility in relation to the present conflict between the medical profession and the Ministry of Health. The in many ways unexpected results of the plebiscite will have heightened their sense of responsibility and at the same time confirmed the confidence of the representatives in the policy they have followed. It was said in the early days of the war, we believe by Mr. Winston Churchill, that it was undesirable to introduce controversial legislation during the period of war stress. But the reformer always seizes upon the atmosphere created by a war to promote those projects which he fervently believes will promote the well-being of the country. It was in 1942 that Sir William Beveridge (as he then was) introduced his Social Security Report. We are not concerned here to argue whether security is an ideal likely to bring out the best from a people who have built up a great and beneficent Empire by boldly accepting the challenge which insecurity offers. It may, however, be noted that the Beveridge Report was published at a moment when Britain was faced with the possibility of overwhelming national disaster. Freedom from fear and from want were things that even the most stout-hearted deeply desired. Assumption "B" of the Beveridge Report carried with it the promise of freedom from disease. The psychological moment was indeed ripe for the reception of Sir William Beveridge's great document, and what Mr. Butler has described as "the new social mosaic" was put together by a Coalition Government. If we are to believe what

Socialist spokesmen have said, the pressure for the nationalization of Medicine came from the Labour side of the Coalition, and successive Ministers of Health—Liberal, National, Conservative, and finally Labour—have been busy trying to fit the medical profession into this new mosaic.

The medical profession has for centuries, and with startling success during the past hundred years, laboured to free humanity from disease and to promote the health of the individual. Doctors hardly needed to be told that this was an ideal to be aimed at and were eager to explore ways in which their beneficent activities could be made more effective. The opposition that the medical profession has offered to successive proposals by Ministers of Health belonging to different political parties clears it from any accusation of party political bias. The opposition is directed against the political control and management through a bureaucracy of the art and science of Medicine and against the employment of medical men by a member of His Majesty's Government. Medicine has never claimed immunity from constructive criticism, or that its services to the community are incapable of improvement. Though individual doctors, through human weakness, may have faltered, each generation of medical men has remained faithful to its high ideals and through this has brought Medicine to the present high position it holds. No one has denied the need for the State organization of such communal services as are provided through the Public Health Acts. But to try to fit the care and treatment of the individual patient by the individual doctor into a national framework is a matter of the highest complexity and one which the planners of Medicine are incapable of fully understanding. The sick person must, of course, have confidence in the medical skill of the doctor, and the degree of skill a medical man has depends not only upon himself but upon those responsible for his technical education. As a science Medicine is full of uncertainties, and a good doctor knows its limits. As important to the sick person as the technical skill of the medical man is his quality as a human being coming into one of the closest relationships that exist between human beings. This is something that the planner, thinking along quantitative lines, fails to take into account and is possibly incapable of comprehending.

The results of the plebiscite show the deep-seated doubt all sections of medical men have about the effect upon the quality of Medicine of the State medical service fore-shadowed in the National Health Service Act. There are compelling reasons for keeping Medicine independent of the State. If, however, the people of this country through Parliament, in the face of what we consider to be the better judgment of the medical profession, pursue with success the idea that a paternal State should provide every kind of medical service, then the medical profession must at least see that within the State framework the maximum amount of freedom and independence of the medical man is made secure. In its present form the Act does not provide safeguards for this freedom and independence, and if the Government fails to provide them the National Health Service Act will be an inglorious failure.

STUDENT HEALTH

In recent years an increasing number of physicians have been appointed at British universities and colleges to supervise medical health services, yet nowhere in this country is there a comprehensive service operating to the full extent considered appropriate by the university delegates to a recent conference on student health.¹ An important lead was given in 1944 by the Goodenough Report,² which recommended that universities should set up student health services, and Cambridge has recently appointed Air Vice-Marshal A. F. Rook for this purpose. In 1946 the Social and Preventive Medicine Committee of the Royal College of Physicians recommended arrangements for medical examination, including chest x-ray and annual re-examination during the student's stay at the university, in order to detect physical and mental disabilities and to indicate how advice or treatment should be obtained if necessary. This committee also suggested that arrangements should be made for the medical and nursing care of students who are ill, and drew attention to such matters as diet and lodgings. Though not as yet generally adopted, schemes for the provision of medical treatment are obviously important, but with sickness provided for more attention can be directed to the preservation and promotion of health.

The present position is summarized in the most recent report of the health committee of the National Union of Students. Among 38 universities and university colleges, 57 training colleges, and 33 technical colleges, 42% have no medical examination or certificate at entry, 30% no provision for advice or remedial service, 36% no arrangement for calling a medical practitioner, 39% pay no attention to lodgings, and in 69% there is no examination for tuberculosis. Generally speaking training colleges are better provided for than universities and university colleges; the position in technical colleges is worst. These arrangements as a whole are in marked contrast to those in universities in the United States.

In the U.S.A. student health organizations have benefited by more than twenty years' experience. There the best medical advice in health and sickness has been made available to students, who have in their turn furnished excellent material for the study of normal young adults, particularly as regards standards of measurement and the ranges of normal variation. The Grant study of young men at Harvard is perhaps the best known on this side of the Atlantic, and the rapidly extending literature concerning student health reveals that the interest has shifted from sickness to health. This reorientation of outlook requires a form of training for physicians different in its scope from the traditional one of hospital practice, and it is perhaps noteworthy that in the study of normal personality the terms of psychopathology have often been found less suitable than words in common English usage.

The factors influencing the welfare of students are those of everyday environment and their genetic endowment.

They include such items as the quality of teaching, the cost of food and lodgings, hours spent in travel or queue at eating-houses, pressure of examinations, the wish to justify financial grants, hours of study often self-imposed and excessive, the loneliness of isolated digs, and at the present time for ex-Servicemen the problems of readjustment to civil life. Such factors assume major importance because they impinge on young life still hopeful of attaining full physical stature, sexual maturity, and intellectual power. A physician with responsibility for young adults has a rare opportunity to guide, to reassure, or to warn at the first sign of disorder. Given understanding and an outlook appropriately sympathetic he may create an atmosphere in which difficulties can be discussed rationally and thus be more easily dispelled. Measurements of physique or personality made at the first interview serve as a base-line against which future observation during the student's residence takes on new meaning. With this purpose in view, with or without an added stimulus of research, what might be a monotonous routine examination can become a lively and sustaining activity.

We publish this week a survey by Dr. J. Pemberton of the health of 407 new students. Because examination after entry was made obligatory for all students at Sheffield his survey covers a fully representative group, and from the findings it should be possible to plan for the future. A case may be established for routine dental and ophthalmological examination, and the ready availability of an E.N.T. surgeon is clearly desirable. With regard to mental health, Pemberton found 20% of students were suffering from minor anxiety states or depression. This proportion corresponds with that found by other workers in this field³ and its importance lies in that the majority may be relieved by relatively simple measures, as for example the adjustment of financial grants, or more simply opportunity for discussion and advice. Even more serious psychological disturbances are not uncommon, as the high wastage rate among students who start but fail to stay the course suggests. Though Pemberton reports no example of attempted or successful suicide, such occurrences are frequent enough to constitute a special problem in which community responsibility is deeply concerned. In addition in the words of the report to the Royal College of Physicians, "the development of a psychosis in a student already embarked on his University career may prove to all concerned a major tragedy, which could have been foreseen and perhaps prevented." Its detection is no less important than the early signs of pulmonary tuberculosis. In view of the foregoing remarks the question of the value of routine psychiatric interview may be raised. Experience to date is limited, but at one well-known university in the U.S.A. mental hygiene examinations were instituted as part of the routine health examination of all first-year students. They were, however, discontinued after four years as it was found that students wanting psychiatric help would seek it, whereas those who did not would not be coerced. Results failed to justify the additional organization, work, and cost.

If it is the purpose of university education to encourage the fullest and best use of all human attributes, then

¹ For a full report see the Health Conference, 1947, Oxford.

³ *British Medical Journal*, 1947, 2, 937.

physical and social development should come second only to the cardinal and traditional aim of intellectual development. Many students reach the university to-day with great intellectual achievement to their credit but possessing neither physical nor social maturity. Facilities to develop in both these directions are necessary, not so much for the star performers in any field, who have little difficulty in following their bent, but mainly to foster the powers and enjoyment of the remaining majority. Preliminary surveys suggest that only a small minority balance their studies with regular outdoor activity. For example, it is probable that many students are unable to swim fifty yards, yet even a young person with severe kyphosis and unfitted for most sports may overcome his handicap by learning to swim on his back. Physical exercise need not be limited to the usual field games but may well include mountaineering, dancing, ski-ing, canoeing, beagling, and other activities according to individual taste. It is not generally realized that where compulsory physical education for first-year students has been in force the university authorities have had no easy task in providing facilities for so wide a variety of recreations.

The question of making routine health examinations compulsory, and also physical recreation, has been closely argued. In most universities on the Continent and in the U.S.A. obligatory examination is fully accepted. Some medical officers in charge of student health services in this country may feel that they could be more effective if medical examinations were compulsory. Medical examination of school-children is accepted by nearly all parents as a necessary and useful adjunct to education. Though not exactly compulsory, under the Education Act of 1944 parents can be induced in certain circumstances to allow their children to be examined. Students attending a university are no doubt supposed to be old enough to know what is good for them, and in any case it is one of the primary functions of education to develop a sense of responsibility in young people. It can be said, however, that where medical examination has been made compulsory at a university little if any harm has followed. Student health services, to develop satisfactorily, should have that voluntary spirit which seeks and finds the answer to individual needs.

RHEUMATOID ARTHRITIS—A NEUROLOGICAL DISEASE?

The cause of rheumatoid arthritis remains unknown. Since the disease was differentiated from other forms of arthritis in the nineteenth century many causes have been suggested,¹ and a number of eminent observers have looked with suspicion at the central nervous system. Charcot² and Pierre-Marre were impressed by the bilateral symmetry and centripetal spread of the disease. Weir-Mitchell produced a neurotrophic hypothesis. More recently Speransky in the U.S.S.R. has suggested that the disease is a specific nervous dystrophy, and interest has been aroused in the technique of "spinal pumping" which was first advocated by him. Elsewhere in this issue Savage describes this

method of treatment and reports on the results obtained in four cases of rheumatoid arthritis. Obviously with such a small series nothing conclusive can be said, but it seems unlikely that completely successful results will be frequent.

Of the three ways—psychological, autonomic, and neurological—in which the central nervous system might be involved in the development of the disease the neurological features have received considerable attention in recent months. They include the paresis and atrophy which affect the muscles of the extremities, and the trophic changes associated with disease of the autonomic system. Sundelin³ believes the symptoms indicate that both the central and autonomic nervous systems are involved. He examined the cerebrospinal fluid from 141 patients, and the only abnormality he discovered was a change in the protein level. In 41% there was either a rise in globulin or an alteration in the A.G. quotient, sometimes associated with a rise in total protein. These findings were not connected with the duration, severity, or activity of the disease, nor with the previous administration of gold salts.

Alteration in the cerebrospinal fluid proteins may be related to the cause or to the effects of the disease, and Sundelin refrains from drawing any debatable conclusions. In rheumatoid arthritis it is not unusual to find an abnormal blood-protein value, with alteration of the A.G. ratio and a rise in globulin level. The empirical tests of liver function may be positive, and these probably depend upon a rise in globulins. The cerebrospinal fluid changes may be only a part of a general alteration in protein levels, possibly depending on the position of globulins in the immune response. Combined observations on cerebrospinal fluid and blood would help to clarify this point.

The muscle paresis and atrophy which Sundelin claims to be neurological features might be related primarily to the altered muscle histology. In rheumatoid arthritis muscle biopsy nearly always reveals focal accumulations of lymphocytes, plasma cells, and eosinophil cells around the nerves and in the endo- and perimysium.⁴ If rheumatoid arthritis is a neurological disease, then the C.S.F. findings of Sundelin would suggest a degeneration rather than an infection of the central nervous system.

CERVICAL INTERVERTEBRAL DISK LESIONS

Lesions of the intervertebral disk, with protrusion of some of its substance into the spinal canal, is now a well-recognized cause of lumbo-sacral sciatica. The cervical region of the spine has many anatomical and mechanical features in common with the lumbar region. There is, however, the important difference in the cervical region that the intraspinal neural structures, which here include the spinal cord, are relatively more fixed and the nerve roots have a more direct passage through their intervertebral foramina. In the cervical region there are numerous causes for pain referred to the neck, shoulder, and arm. Kristoff and Odom¹ have studied twenty cases of ruptured cervical intervertebral disk. This type of case was first described by Stookey in 1928 as one of compression due to extraneural cervical chordomas, but it is only in the last few years that much has been written on the subject.

Kristoff and Odom believe that in all probability such lesions are traumatic in origin. Rupture of a cervical intervertebral disk results in some of its substance extruding into the spinal canal, generally causing root compression. Where these protrusions are large the case may be complicated by spinal cord compression. Pain and paraesthesia are of radicular distribution. When the sixth cervical root is compressed by the fifth intervertebral disk the area of distribution will be the radial side of the forearm, thumb,

² *Arch. Physiol.*, 1868, 1, 161.

³ *Amer. J. Med.*, 1947, 2, 579.

⁴ Gibson, H. J., et al., *Ann. rheum. Dis.*, 1946, 5, 131.

and index finger, associated with weakness mainly of the deltoid and biceps muscles and a diminished biceps reflex. A rupture of the sixth disk with involvement of the seventh cervical nerve root will cause pain and paraesthesia on the extensor side of the forearm, the dorsum of the hand, and one or all of the three middle fingers, associated with weakness chiefly of the triceps muscle and a diminished triceps reflex. These are the two segments most commonly involved. A reliable sign is to hyperextend, flex, and bend the head towards the side of pain—manœuvres which aggravate it and the paraesthesia. Radiologically, degenerative changes in an intervertebral disk may be recognized, but their absence by no means rules out the possibility of a disk lesion.

The common conditions which may cause difficulty in diagnosis are cervical arthritis, scalenus anticus syndrome, laminal fractures, cervical ribs, subdeltoid bursitis, brachial neuritis, Pancoast's tumour, and cervical radiculitis. In the cases with larger protrusions the need for exploration is clearer because of the signs of spinal cord tumour. Here the pain in the neck or shoulders will be overshadowed by neurological changes in the upper limb. The operative procedure in the neck is somewhat similar to that for the lumbar region, but there is of course a bigger element of risk. The authors note that, while both the subjective complaints and the defensive signs will be banished by removal of the protruding portion of disk, disappearance of the neuro-pathological signs depends upon the duration of root compression. Furthermore they state that in cases of cord compression recovery may be neither spectacular nor always complete. They give a very clear exposition of this subject, the limits of which seem to be more clearly marked than in the comparable condition in the lumbo-sacral area.

ALUMINIUM PNEUMOCONIOSIS

Powdered aluminium has been very widely used during the past decade in ordnance factories and in making paints, and many thousands of workers have been exposed to dust in working aluminium alloys. The health of the workers in these industries has been generally satisfactory. Crombie and his colleagues¹ in Canada, and Hunter and his co-workers² in England, have been unable to demonstrate radiologically any changes in the lungs. This is only to be expected because of the low atomic weight of aluminium. Since Denny, Robson, and Irwin³ suggested that the inhalation of powdered metallic aluminium might prevent the development and progression of silicosis large numbers of miners in Canada, the United States, Australia, and Cornwall have received the treatment. These men have all been under careful observation, and up to the present no adverse effects have been recorded.

Despite this experience Goralewski,⁴⁻⁶ in Germany, has repeatedly described a disease attributed to aluminium dust. The powder was made at Gunterstahl by the Pyro process. It was stamped, but a minimum of either ceresine or petroleum-jelly substitute was used to lubricate the powder in the stamping machines—not more than 0.01% appeared in the final product. The aluminium powder, which was 98% metallic aluminium, contained about four milliards of particles per gramme of dust—97.5% of the particles being less than 5 μ in diameter—and many of the factories were blown up because an explosive concentration of aluminium dust was reached. Seven hundred workers were examined, and many complained of dry cough with pain on breathing.

shortness of breath, poor appetite, and gnawing abdominal pain. Spontaneous pneumothorax occurred in four workers. Blood counts revealed a relative lymphocytosis with an eosinophilia up to 10%. The sedimentation rate was within normal limits in 78% of the cases, and the vital capacity was decreased in 27 out of 125 men examined. Radiographs showed focal shadows in the apical region with an increase of normal bronchial markings in the upper and middle thirds of the lung, giving a reticular appearance which at a later stage tended to increase and become confluent. There was always marked emphysema at the bases. The development of the illness was rapid, often within three months of starting work. It appeared to bear no relation to the length of exposure to aluminium. Histological examination of the lung of a patient who died revealed coarse, branching, hyaline collagenous fibres which enclosed phagocytes containing fine and coarsely granular particles distinguished by their jagged outline from carbon particles. A similar picture was produced in animal experiments by Jötten and Eickhoff.⁷

Shaver and Riddell¹⁰ have now recorded an identical disease from the Niagara region of Canada in workers manufacturing corundum—an aluminium oxide abrasive of great hardness. Bauxite, iron, and coke are treated in electric furnaces. They are ground and intimately mixed in metal pots 6 ft. high and 6 ft. in diameter; large carbon electrodes are then lowered to the surface of the mix, which is fused at 2,000° C. The resultant dense white fumes contain considerable quantities of alumina and silica together with small quantities of many other substances all in a very fine state of division. Three hundred and forty-four men were employed in connexion with the furnaces, and in 23 of these x-ray examination revealed well-established changes in the lungs. There were also 12 early and 13 doubtful cases. There have been 7 deaths, and 8 of the workers have had bilateral spontaneous pneumothorax. Dyspnoea was the outstanding symptom. Cough with white frothy sputum, substernal discomfort, weakness, and fatigue were also noted. The attacks of dyspnoea and pain were often sudden. Signs of disease in the chest were variable and depended on the presence or absence of pneumothorax. Limited chest expansion and impaired percussion note were most commonly observed; rales and rhonchi were variable. Tachycardia and cyanosis were marked features. X-ray examination revealed extensive fibrosis with areas of gross emphysema. At necropsy emphysematous blebs and bullae were found on the surface of the lung, the substance of which was invaded by dense tissue of a fibrous character. Microscopically the chief features were extensive fibrous tissue formation and extreme emphysema. The fibrosis was not nodular. The result of ashing three lungs was:

	Ash of Dry Weight	Silica of Dry Weight	Silica in Ash	Alumina in Ash
1	5.87	1.49	25.3	Not obtained
2	7.22	1.80	24.9	45.63
3	9.66	2.95	30.5	32.08

Jager and Jager¹¹ observed that while aluminium powder is highly resistant to aerial oxidation it is freely soluble in sodium chloride solution, giving sodium aluminate and aluminium chloride in equilibrium. A colloidal aluminium hydroxide complex results if the sodium and chloride ions are allowed to diffuse away, and if protein is also present:

¹⁴ *Perry, K. M. A., Thorax*, 1947, 2, 91.

it is co-precipitated round the partly dissolved aluminium particles. Jager and Jager think that this complex caused the lung changes in the German workers. Koelsch,¹² however, believed that mechanical factors were responsible, and that the disease was a consequence of the unsatisfactory ventilation of workrooms resulting from the black-out. The suggestion has also been made that the lubricant might have been a cause of the condition,¹³ but this seems improbable since only minimal amounts were used. Canadian investigators think that the disease may be a form of silicosis caused by vaporized silica, but this also seems unlikely. There can be little doubt that the disease described in Germany and that in Canada are one and the same, and while silica was present in the Canadian manufacturing process it certainly was not in the German. The exact aetiology of the condition therefore remains a mystery, but it now seems probable that aluminium in certain physical states is capable of producing a pneumoconiosis.

RESECTION OF TUBERCULOUS LUNG TISSUE

In 1891 Tuffier successfully removed an indurated tuberculous area from the upper lobe of the lung, his patient surviving for seven years. Since then sporadic reports of similar operations have appeared, but until the last decade the successes were outnumbered by the failures, most of which were due to the great technical difficulties. With the rapid advance of thoracic surgery in the past few years many of these difficulties have been overcome, and thoracic surgeons, particularly in the U.S.A., are reporting an increasing number of successful pulmonary resections for tuberculosis.

Overholt and others,¹ in an important communication, record 88 resections with a follow-up ranging from 2 to 12 years. Their indications for operation were varied, the commonest being extensive, predominantly unilateral disease. Many patients had spreading caseous-pneumonic lesions or large cavities at the time of operation. Resection was also undertaken for bronchiectasis and suppuration complicating phthisis, and after unsatisfactory thoracoplasty. Tuberculous bronchial stenosis was present in many instances. Lobectomy was performed in 34 patients, with 7 deaths, the most important complication being a spread of the disease into the remaining lobes. Of 58 patients who had pneumonectomy 24 died, and again spread of tuberculosis into the remaining lung accounted for many of these deaths. Other complications were tuberculous empyema and ulceration of the severed bronchus. Against this somewhat grim picture must be set the fact that 12 patients with lobectomy and 24 with pneumonectomy are reported to be well and working; also in many of these patients the risk of operation was a desperate one. In a more recent paper Bailey² reports the results of 80 pulmonary resections for tuberculosis. His mortality for lobectomy was 8 out of 32 cases, and for pneumonectomy 15 out of 41. Seven segmental resections were performed without a death. Like Overholt he advocates the routine use of thoracoplasty after pneumonectomy in tuberculous patients to close the residual space—a procedure which makes the operation more severe. Both these authors stress the importance of surgical and anaesthetic technique in the prevention of complications, and it is clear that these operations should be undertaken only by a skilled thoracic surgeon working with a trained team.

When considering the indications for pulmonary resection we must not forget that in tuberculosis we are dealing with a widespread infection of which the lung lesions are, in Sir Robert Philip's words, "a late visceral manifestation."

In carcinoma of the bronchus or bronchiectasis radical removal may be achieved, but in tuberculosis the most that can be expected is that the removal of some of the major foci may enable the patient's resistance to overcome the less obvious lesions. It is not surprising that such a severe procedure may sometimes have the opposite effect and exacerbate latent disease elsewhere. Nevertheless, this operation offers a possibility of improvement in a few types of pulmonary tuberculosis in which the prognosis has hitherto been almost hopeless. These include suppuration distal to a tuberculous bronchial stenosis, basal disease unaffected by simpler methods of treatment, large tension cavities, and a few instances of acute unilateral caseous disease.

THE ACTION OF BOTULINUM TOXIN

There are few poisons so potent as botulinum toxin. According to Guyton and MacDonald¹ a pure crystalline preparation would probably prove fatal to man in a dose of a quarter of a millionth of a gramme. These workers have recently thrown light upon the site and mode of action of the toxin, their technique being designed to produce complete paralysis either of a single muscle or of the whole animal. The gastrocnemius of a guinea-pig could be paralysed by the local injection of toxin, general paralysis and death of the animal being prevented by systemic administration of antitoxin two days later. In the other method systemically poisoned and completely paralysed rabbits were kept alive by artificial respiration and vasoconstrictor drugs for the duration of the observations, which consisted in measurement of action potentials and responses of the muscles to various stimuli. The experiments were made with type A toxin.

There was no evidence that botulinum toxin acted on the nerve trunks, and the paralysed muscles responded to direct stimulation in the same way as denervated muscles. The site of action is therefore in the terminal nerve fibrils or, as Bishop and Bronfenbrenner² suggest, at the myoneural junction. Oscilloscopic measurements of the delay in conduction, recorded by Guyton and MacDonald, support the theory that the myoneural junction is affected, and histological examination shows swelling of the end-plates and dissolution of the granules of Kühne. Neostigmine fails to avert paralysis due to botulinum toxin, and the completely paralysed muscles still respond to acetylcholine. In these respects the action of the toxin differs from that of curare. It seems probable that in botulinum poisoning acetylcholine is not produced at the end-plate or, from the evidence of other experiments, at the endings of the vagus nerve. The toxin also causes peripheral circulatory failure. It does not pass the blood-brain barrier, so that symptoms referable to the central nervous system are not observed. It has a molecular weight of about 1,000,000, and its properties suggest that it may be a destructive enzyme.

It is of interest to note that antitoxin given two days after the subcutaneous injection of a lethal dose of toxin saved the lives of guinea-pigs even after some symptoms of intoxication were present. Once poisoning of nerve endings has occurred antitoxin cannot restore the damaged end-plate. Observation of local paralysis in guinea-pigs showed that recovery of muscular contraction and action potential was almost complete in one year. From the nature of the damage and the prolonged time to recovery noted in the experimental animals improvements in the treatment of botulism in man are unlikely, and hope seems to lie mainly in the early use of multivalent antitoxin in large doses.

TUBERCULOSIS IN THE BRITISH ZONE OF GERMANY

REPORT OF AN INQUIRY

The Foreign Office published on Tuesday, March 9, a report prepared by the Medical Research Council at the suggestion of the Ministry of Health on certain aspects of the tuberculosis problem in the British Zone of Germany. The authors of the report are Dr. M. Daniels and Dr. P. D'Arcy Hart.

The report points out that death rates form the most reliable basis for judging tuberculosis trends. Annual death rates are best, but over the comparatively short post-war period six-monthly figures may justifiably be used provided that a first half-year is not compared with a second half-year, since the death rates from tuberculosis are normally higher in the first half of the year. During the post-war period the death rate from pulmonary tuberculosis in Hamburg has declined, while in the three Laender the figures show little evidence of change. The death rate from non-pulmonary tuberculosis has also declined slightly in Hamburg, remained stationary in Schleswig-Holstein, and increased somewhat in the other two Laender. The relevant figures for the Zone as a whole are as follows:

Tuberculosis Mortality, 1946-7, in British Zone as a Whole

Half-years	Population	Deaths		Crude Annual Death Rates per 100,000		
		Pulm. Tb.	Other Tb.	Pulm. Tb.	Other Tb.	Tb. All Forms
1946 I	21,891,000	6,823	891	62	8	70
II	22,902,000	5,083	801	44	7	51
1947 I	22,868,000	6,966	1,096	61	10	71

Clearly, while no fall in tuberculosis mortality has taken place, there are no signs of any alarming increase. These figures should also be considered in relation to the rates existing before and during the war. The 1946 death rates are higher than the pre-war rates, but the main rises occurred during the war period. Indeed, in Hamburg and part of Nordrhein-Westfalen the war rise appears to have been checked in 1945. Death rates in the British Zone are very similar to those in the United States Zonal Regions, which in 1946-7 ranged from 49 for Bavaria to 91 for Bremen. The crude death rate from all forms of tuberculosis in Bremen should be compared with the Hamburg figures of 101 in 1945 and 85 in 1946. The corresponding figures for London in the same two years were 87 and 70. The rates for Hamburg in fact are considerably less than those obtaining in Glasgow and Liverpool, and in Paris, Warsaw, and Rome.

The proportionate tuberculosis mortality, the number of deaths which occurred from this disease expressed as a percentage of annual deaths from all causes, also confirms the view that tuberculosis does not figure more largely among health problems in the British Zone of Germany than in Great Britain. The figure for England and Wales for 1945 was 4.8% as against 4.2% in Niedersachsen and 4.5% in Schleswig-Holstein in 1946. The figure of 5.7% in Hamburg in 1946 may be compared with the 1945 figures for London 5.5% or for Manchester 6.4%.

Registration and Notification

In the British Zone there are two methods of reporting deaths, and in certain small towns and country districts lay people can complete death certificates. Attention is drawn to the difference in Schleswig-Holstein between the uncorrected total of 2,746 registered tuberculosis deaths in 1946 and the corresponding "verified" total of 1,655. Where medical certification is compulsory the figures of registered deaths are regarded as a fairly correct measure of tuberculosis mortality. Apart from this method of registration of a death, deaths from tuberculosis must be notified by the medical practitioner directly to the health police of the Health Department. This is not always done, however, and the total notifications of deaths from tuberculosis tend to be less than death registrations.

Four suggestions are put forward for improving the value of the mortality figures supplied to Regional Public Health Branches. (1) Tuberculosis death figures (pulmonary and non-pulmonary) should be supplied quarterly instead of weekly as at present. (2) These quarterly figures should be derived from registered deaths and so stated, the figures being "officially verified" where this procedure is necessary. (3) Tuberculosis death registration figures should be accompanied by figures for deaths from all causes, so that proportionate tuberculosis mortality figures can easily be calculated. (4) The German Land authorities should be persuaded "to make medical certification a prerequisite of burial throughout their territories."

Tuberculosis Morbidity

The fact that tuberculosis mortality rose during the war but has altered very little since then and that the present rates are not disturbing when considered in relation to those in Britain and other countries was not disputed by the German authorities. All of them emphasized, however, the considerable increase in morbidity in the past year. The report points out that since 1925 there has been in fairly general vogue in Germany a classification of cases of pulmonary tuberculosis requiring care into three groups: (a) infectious tuberculosis of the lungs with bacilli discovered; (b) infectious tuberculosis of the lungs with no bacilli discovered; and (c) non-infectious but active tuberculosis of the lungs. The recent remarkable rise in practitioners' case notifications is simply explained, and the report confirms the suggestion made in our columns that the rise was almost entirely due to a change in the methods of notification (*Journal*, Feb. 28, p. 424). Until 1938 doctors notified cases in group (a) only. From December, 1938, to September, 1946, doctors notified cases in groups (a) and (b) only. Since September, 1946, practitioners have notified cases in groups (a), (b), and (c). The recent steep rise in pulmonary tuberculosis case notification rates represents therefore largely a "paper increase." The recent extension of notifications has gone far beyond the original intention of bringing in fresh categories of cases of tuberculosis so as to give a more accurate picture, and has allowed the notification of many equivocal cases that would not be notified in British practice. It is shown too that a wide definition was being variously interpreted by different authorities and by different physicians. An incentive to exploit the definition now permitted is provided by the entitlement of dispensary-approved cases to extra rations. For these and other reasons which are set out at length the two investigators concluded: "We must state categorically that we attach no significance whatever to statistics of pulmonary case notifications as an index of current tuberculosis trends in the British Zone."

These objections do not apply with the same force to the regular returns made by tuberculosis dispensaries to the Local Health Departments. All three categories are again included and under (c) there were notified doubtful active cases, children whose radiographs merely showed "enlarged hilar shadow," and even clinically normal infants with positive tuberculin reactions. On the other hand, these dispensary registration figures are based on specialist opinions and the pulmonary cases are subdivided at source into categories (a), (b), and (c) so that the numbers may be considered in each category. An analysis of the dispensary statistics of new cases registered over a number of years in Hamburg, Hannover Province, and Schleswig-Holstein shows no marked increase since the end of the war in the more serious forms of pulmonary tuberculosis—(a) and (b)—but a considerable rise in the registration of those earlier or lesser forms represented by group (c). There has also been a recent rise in new non-pulmonary cases of tuberculosis.

At the end of 1946 there were 200,000 cases on the tuberculosis dispensary registers of the British Zone. The report points out that at the end of 1946 there were 244,000 cases of tuberculosis on the tuberculosis dispensary registers of England and Wales, with a population nearly twice as large. The British total, however, is based on criteria which exclude the German category (c) in which there were 12% of the British Zone cases. To improve the dispensary figures it is again suggested that case figures should be supplied quarterly, that they should comprise only cases newly notified and registered on the books of the tuberculosis dispensary.

and that they should be tabulated under the customary groups. These returns should contain only definite cases and should exclude suspects, contacts, and otherwise normal tuberculin-positive children. A survey of the findings after mass radiography in three areas also suggests that the incidence of tuberculosis is not notably high.

Hospital Accommodation

It is customary to assess the degree of adequacy of in-patient accommodation for tuberculosis by the ratio of the beds available to the annual number of deaths from the disease. This rate for the Zone as a whole is 2.2 and should be compared with 1.3 for England and Wales. It also compares favourably with the rates obtaining anywhere in Europe, excepting Scandinavia.

Detailed comparison of the arrangements in Lancashire, a county with an advanced anti-tuberculosis service, bears out the finding that "on no count, therefore, is the British Zone worse off than this country as to institutional accommodation; and on the most reliable basis of ratio of beds to annual deaths, it is considerably better."

Two further points are made in the report on the Zone. The fact that tuberculosis mortality increased more among males than among females during the war is ascribed partly to a selective factor—healthy young men were enlisted and the statistics relate, therefore, to the remaining male population—and partly to the greater strain of wartime conditions borne by males. The increase in the mortality from non-pulmonary tuberculosis and in the incidence of new cases is probably due to a failure of efficient pasteurization. Much of the pasteurization plant was damaged during the war and it has since then been subject to general deterioration and reduced efficiency. Fuel shortages have also made pasteurization difficult.

Tuberculosis in Berlin

Although the main study was in the British Zone the position in Berlin was also investigated. The increase in tuberculosis mortality during the war was much greater in Berlin than in the Zone. The present level of mortality is also much higher and constitutes a grave problem, even though the mortality from non-pulmonary tuberculosis is at present stationary and the mortality from pulmonary tuberculosis appears to be declining. Institutional provision for the tuberculous in Berlin at a rate of 0.7 beds per annual tuberculosis death is much inferior to that of the British Zone. The actual number of cases of "active" tuberculosis on the dispensary registers in Berlin in August, 1947, was 79,331 in a population of 3.2 millions. It was made up of 11,694 cases in group (a); 9,893 in group (b); 9,673 in group (c); and 8,071 non-pulmonary cases. Even allowing for the questionable significance of group (c) this total is two and a half times the corresponding pre-war total incidence and is much higher than that in the Zone.

This is an important report and one which should be carefully studied. It amply confirms the statement made in our leading article (Nov. 30, 1946, p. 821) that "available figures do not bear out alarmist reports of the incidence of this disease in the British Zone." The detailed survey and the tables and graphs fully support the general discussion which is here summarized, and confirm a final statement made by the authors:

"We must refer here to the regrettable fact that German officials (some non-medical) have repeatedly during the past year issued to Allied journalists and other visitors misleading and sometimes even false information regarding the tuberculosis situation in Germany. These statements have had the effect of putting tuberculosis in Germany unjustifiably on the level of a sensational news item. Moreover, since it is generally known that tuberculosis figures are a sensitive index of social conditions, sweeping conclusions as to these conditions have been drawn from erroneous data."

The head of the U.S. Federal Security Administration, Mr. Oscar King, estimates that in 1960 the U.S.A. will need from 15,000 to 20,000 more doctors than will be available, and he recommends the establishment of Government financed scholarships for the training of medical men, dentists, nurses, and public-health staff. He said that Congress ought to use Federal resources if necessary to overcome shortages.

WORLD HEALTH ORGANIZATION

INTERIM COMMISSION

The Interim Commission of the World Health Organization met in Geneva from Jan. 22 to Feb. 7, under the chairmanship of Dr. Andrija Stampar, president of the Yugoslav Academy of Sciences and Arts. In the course of this session the Interim Commission approved a report on its activities which will be submitted to the World Health Assembly meeting at the Palais des Nations in Geneva on June 24. It is generally expected that the Interim Commission, which has bridged so ably the unexpectedly long gap between its creation at the International Health Conference in New York in 1946 and the first meeting of the World Health Assembly, will be formally dissolved within one or two months of the adjournment of the Assembly.

The Interim Commission drafted the agenda for the Assembly, which will have to select a Director-General for W.H.O., and also examined proposals relating to the permanent site and the 1949 budget for W.H.O. A number of nations have already declared their preference, and so far Geneva heads the list, with New York, Paris, Washington, and London as alternative suggestions. The proposed 1949 budget amounts to \$6,367,995, which is more than twice the Interim Commission's budget for the first year of its work. Of this sum, over \$1,000,000 will be set aside for the provision of fellowships, medical literature, teaching equipment, and emergency medical supplies.

Proposed Programme

The following are among the major recommendations of the fifth session of the Interim Commission, and will in due course be submitted to the World Health Assembly:

Medical co-operation with accredited governmental and non-governmental agencies should be continued. It was recommended, therefore, that the Assembly adopt the draft agreements drawn up by the Interim Commission with several United Nations Specialized Agencies. These agreements provide that the W.H.O. shall serve in an advisory capacity in the fields of public health and State medicine with the following organizations: the International Civil Service Advisory Board, the U.N. Social Commission, the U.N. Scientific Conference for the Conservation and Utilization of Resources, I.L.O., U.N.E.S.C.O., and F.A.O. Collaboration between W.H.O., I.C.S.A., and F.A.O. on nutrition projects has already started.

The Interim Commission, which is collaborating with the International Children's Emergency Fund, will continue to advise the I.C.E.F. on the programme for immunization of 15 million people against tuberculosis to be undertaken by 200 expert medical teams within the next eighteen months. At the fifth session Interim Commission help was requested by the I.C.E.F. in launching an antiveneral campaign among children, pregnant women, and nursing mothers through mass treatment with penicillin. Continuation of medical guidance by the permanent W.H.O. was recommended in relation to these two programmes.

The Interim Commission recommended continuation and enlargement of the epidemiological service. A more efficient and quicker system of epidemiological notifications will be established.

In addition to these major projects it is hoped that the 1949 budget will provide for further work in connexion with nursing, rural hygiene, alcoholism, and a number of tropical diseases. The need for revision of existing sanitary conventions was debated after Dr. A. T. Shousha Pasha, the Egyptian Under-Secretary of State for Health, had presented his report on the 1947 cholera outbreak in Egypt. Several countries took measures to prevent the spread of cholera far exceeding the provisions of the international conventions. The Governments concerned will be asked to explain the scientific grounds on which such action was based.

The Interim Commission also recommended the continuation of work on biological standardization and unification of pharmacopoeias. The creation of an international influenza centre is now well under way, and it is suggested that W.H.O. should press forward also the campaigns against important communicable diseases and for the promotion of child health. Malaria and tuberculosis are the two diseases given "top priority" in the list of Interim Commission recommendations, and the large-scale application of penicillin in the treatment of early syphilis is also proposed.

At the final meeting Dr. Stampar paid tribute to the work of the Interim Commission over the past twenty months and said

that "never in his experience had he worked with a more co-operative and internationally minded group of people." He referred also to the unbroken record of unanimity in decisions made by the Interim Commission.

THE HUMAN APPROACH

METROPOLITAN COUNTIES BRANCH LECTURE

Another lecture in the series which the Metropolitan Counties Branch has arranged for senior students and newly qualified practitioners in the London area was delivered in the Great Hall of the Association on March 2 by Dr. Henry Yellowlees, whose subject was "The Human Approach." Dr. R. W. Cockshut, chairman of the Branch Council, presided.

Dr. Yellowlees began by contrasting the scientific and the human approach. The scientific method, he said, was by far the best yet evolved for the solution of certain kinds of problems, but there remained a vast number and variety of problems in which the scientific method could lead only to an incomplete solution or offer no solution at all. Properly used, the scientific method never led to an erroneous conclusion, because it was wisely agnostic. In everything outside pure mathematics scientific conclusions were tentative and incomplete. Science was always right, so far as it went, but there were other methods of approach which transcended it. Science was never inaccurate, but it was often pathetically inadequate.

The preclinical subjects were peculiarly suited for approach by the scientific method. Things like the sphenoid bone and the cranial nerves simply had to be learned and learned well, and that was that. But then came the clinical period and a crowd of problems which the scientific method unaided could not solve. The student passed suddenly from the laboratory and the dissecting-room to the hospital ward and the out-patient department. He was invited to deal with minds and personalities. This was called clinical material, but it did something which the specimens in the laboratories never did, it "answered back." He wondered how many of them could say that before they entered on their clinical period they had received any helpful and practical instruction on how to understand and deal with those qualities in their patients which chiefly distinguished them from the beasts of the field.

Limitations of the Scientific Approach

It had often been pointed out, Dr. Yellowlees continued, that the trend of modern medical practice and teaching was increasingly towards laboratory procedure and tests. Much of this was inevitable, and the accuracy and helpfulness of the information were not to be disputed. Its chief drawback was that the student might come to feel that the hospital physician had only to acquaint himself with the relationship of a mass of typed reports from the pathologist, the haematologist, the radiologist, the biochemist, and finally to pronounce a diagnosis largely based on their collective significance. The student was led to think that any personal investigation of the patient should be withheld so long as one single secretion or function remained untested by the experts of the clinical laboratory or the special departments, while the patient himself perambulated wearily from department to department like a "passed to you" memorandum in a Government office. This was a continuation of the scientific approach which had served the student excellently in his earlier subjects but failed him now.

The student got little help from his teachers. They had seen the human body separated out into little regions, each with its guardian angel in the shape of its appropriate specialist. It might be said that this was the time for the teachers in psychological medicine to get busy and set things right. Generally, he agreed; but at the present day the teaching of psychological medicine was lopsided and inadequate. True, psychological medicine could put up a good case for the defence. Teachers, students, doctors, the general public, all tended to sheer away from the whole subject of psychological medicine with dislike and distrust. This feeling was based on ignorance, and the ignorance was closely bound up with fear and shame, camouflaged of course, but thereby making itself only the more

obvious. What would one think of a person whose funniest stories concerned the patients in a cancer hospital, or who screamed with laughter at the helpless gropings of a blind man? Yet jests about the "loony bin" remained a characteristic English sport. No brutality was intended; nevertheless he could think of only two types of establishment, apart from the mental hospital, which had analogous alternative names—the prison and the brothel.

General medicine looked with dislike and distrust on a speciality which might help it to a viewpoint it could not reach unaided. Some, indeed, called for a closer union between general and psychological medicine, but he felt with regard to much of this that the scripture was appropriate: "This people honoureth me with their lips but their heart is far from me." Exhaustive examinations were made of the lungs, the circulatory system, the digestive tract of the patient, and treatment was carried out, without a word being said about the psychological factor from start to finish, or any suggestion that it mattered in the slightest whether the patient was happy or miserable, clever or stupid, married or single, Briton or Hottentot. But every now and then the patient ceased to act like a machine and behaved not according to plan, and then they tried out the old fallacy of excluding the organic factor. As someone had said, it was not of much use talking about psychosomatic medicine if all that one did was to give an airy wave of the hand to *Psyche* as one passed along for a heart-to-heart talk in a quiet corner with *Soma*.

A Unique Speciality

At the same time Dr. Yellowlees admitted that the psychiatrist very often made "shockingly poor use" of such chances as he got, usually because he was attending too much to his own scientific problem to the exclusion of the human one. He was by no means blameless for the fact that his speciality had become a "public joke." Psychiatry, of course, had its scientific problems like all branches of medicine, and it was only fair to say that it had solved many of them brilliantly during the last twenty years. With the possible exception of anaesthetics, no branch of medicine could point to anything like the record of startling and revolutionary achievements. But psychological medicine had gone the same materialistic and mechanical way as general medicine, with less excuse and with even more tragic results. At present it was the most scientific and least human of all the specialities.

Psychological medicine was unique among the specialities. It was not only a speciality in its own right but also an essential constituent part—not a mere handmaid or hanger-on or poor relation—of all medicine. But as taught to-day it did more to illustrate the differences between itself and general medicine than to emphasize their essential unity. Generation after generation of medical students were allowed to pass through the schools without having heard the human approach to the patient so much as mentioned. "What is the use of cramming the student with the details of every medical and surgical and psychiatric procedure if he does not then know how to say 'Good morning' properly to a nervous patient?" Of course the scientific study of every branch of medicine was absolutely essential. The patients would take scientific skill for granted, but what they really wanted, whether they knew it or not, was someone who, in addition to knowing his work, could give them confidence, patience, courage, and hope. "The great majority of our patients, in their hearts, whatever they may say and do, expect us to be to them 'like the shadow of a great rock in a weary land.'"

At the annual general meeting of the Scottish Council for Health Education held on Feb. 20 at Aberdeen it was reported that public interest in health education throughout Scotland was noticeably on the increase. During 1947 a total of 252 meetings were held in Scotland, attracting an attendance of 64,483 persons—eight of them with an attendance of 14,900 being held in Edinburgh, where the Corporation organizes and finances a winter series of film-and-lecture meetings. The Council's full-time medical lecturer, Dr. Kenneth I. Macleod, has addressed 212 meetings in six months. Visits to schools are a regular part of his daily itinerary, but he also gives talks to youth clubs, industrial workers, and women's organizations. The 55 major local authorities in Scotland now support the Council.

TOWARDS THE IDEAL HOME

Until March 25 some corrective for present depressions will be afforded by the Ideal Home Exhibition at Olympia, most conspicuously in the official exhibit in which the Ministries of Health, Education, Food, and Labour and National Service have combined. They have concentrated on a demonstration by tableaux, photographs, and poster displays of the services directed towards the welfare of the child from the intra-uterine to the adolescent phase. The child of to-day is to be sympathized with in some respects, but he has only to look across a hundred years to the dark age of the industrial revolution to thank his stars that he was not born then, at all events in a working-class environment. A plaster figure of a child working in a coal mine, and the suggestion of child labour in factories and mills, of starvation and neglect in work-houses, of flogging and ugly and unhealthy conditions in schools, of under-nourishment and overcrowding in the home, are contrasted with present-day conditions. These include health services for expectant and nursing mothers and young children, maternity grants, family allowances, and supplementary rations. There are school medical services and school meals, and the juvenile employment service, which endeavours to ensure that the adolescent enters an occupation for which he is fitted and for which he has some preference. The work of the special schools for blind, crippled, and delicate children and of the nursery schools is also exhibited. Statistics attractively presented bear out the same story, showing the reduction of infant and maternal mortality. One chart illustrates the milestones in the children's health service from 1862, when health visiting began.

In another exhibit the Ministry of Health depicts the housing achievements of the nation since the end of the war. The first 200,000 permanent houses have been finished and are occupied in various parts of the country, and models are shown of concrete, brick, or aluminium dwellings—three-bedroomed houses for the average family. Among other exhibits which catch the eye is a pavilion where the National Gas Council, by means of domestic interiors and life-size models, shows the uses of the newly nationalized product in what it calls the seven ages of woman. One of the tableaux shows the young woman entering upon her career as a hospital nurse and discovering to what extent gas and its by-products (drugs, dyes, plastics, disinfectants) enter into the hospital service; then we have the housewife with her enamel cooker thermostatically controlled, her refrigerator, and other equipment for the labour-saving kitchen, and finally the old dame with the comfort of her gas-coke fire. Not to be outdone by its older rival, the electrical industry shows its fluorescent light-fittings for the home, together with some ingenious space-heating equipment.

DAYLIGHT VERSUS ARTIFICIAL LIGHTING

The Illuminating Engineering Society staged an amusing, if sometimes inconsequent, debate recently on the proposition that artificial lighting is an adequate substitute for natural lighting. The proposer, a lighting engineer, claimed boldly that artificial light is not merely a substitute for daylight but an improvement upon it. If the lighting effect of the sun could be considered in isolation, apart from heat and power, it would be seen to be easily outdone by the fluorescent tube. Moreover, the lighting engineer could provide an adequate and even lighting for the twenty-four hours of the day as against a limited and varying daylight. Another speaker pointed out that an advantage of artificial light was that its colour could be changed, so as to stimulate or to soothe according to the need and the hour of the day, whereas with daylight there was no such control. If artificial light had been first in the field, said yet another speaker, if the fluorescent tube, the splendid product of years of research, had preceded the sun, people would have derided the latter when it at length arose, asking what was the use of so uncertain and wayward a source.

The sun had its defenders. Artificial light, said its spokesman, compared poorly with daylight, whether judged from the psychological, the aesthetic, or the efficiency point of view. The public showed its preference for daylight whenever it was given the chance. The blackout during the war caused much

discontent among factory workers, however good the artificial illumination provided, and the discontent was assuaged by the letting in of some natural lighting. The fluorescent tube, these speakers contended, was a hideous thing—a cold bar of light apparently designed by a plumber. How magnificent a thoroughfare was Kingsway in daylight, and how grotesque at night under its new illumination with fluorescent tubes hung skittishly on concrete pillars. The protagonists of artificial lighting had said that windows were put into buildings, not to give light, but to give a sense of freedom and the opportunity for gazing out; but what array of electric bulbs could rival the light given by the Gothic window of a church or by the Victorian or neo-Georgian window of domestic architecture? One speaker had written to the welfare officers of certain American factories which were lighted only by artificial light, and they had replied that the lighting was liked moderately well, chiefly because it was uniform. But in this country, at least people took a poor view of uniformity and found variety stimulating, alike in lighting and in climate. One speaker argued that there was something in the human make-up which demanded change, alternation, rhythm in lighting, and that the same was true even of lower forms of life.

The last word was with the defenders of daylight, one of whom said that on a recent visit to New York he found on the outskirts of the city very tall buildings of many stories still being constructed, but they were well spaced out so as to ensure even for the lower floors an abundance of daylight.

Reports of Societies

INHIBITION OF DENTAL CARIES BY FLUORINE

At a meeting of the Section of Odontology of the Royal Society of Medicine on Feb. 23, with Prof. HUMPHREY HUMPHREYS in the chair, Dr. ROBERT WEAVER, of the Medical Branch, Ministry of Education, read a paper on the inhibition of dental caries by fluorine.

Dr. Weaver said that in the early 'thirties it was suggested that a mottled appearance of tooth enamel was caused by the presence of a substantial amount of fluorine in drinking-water. It was not at that time realized that a very much lower concentration of fluorine than was necessary to produce mottling might inhibit dental caries. During the five years before the war, however, evidence accumulated that the inhibition of caries could be brought about by a concentration of fluorine too low to cause any unsightly mottling. In 1944 Dr. Weaver himself had referred to the low incidence of dental caries in certain areas as being possibly due to fluorine, and the evidence accumulated since then had convinced him that judgment on this point need no longer be in suspense.

Fluorine was by no means a rare element. It was now being used widely for industrial purposes, but there were few communities of any size dependent for water supply on water containing significant amounts. Most fluorine-free waters were soft; well-waters, in which fluorine was more likely to be found, were hard. The fluorine content of the diet, apart from drinking-water, was, generally speaking, low. It was relatively high in fish, perhaps up to 7 parts per million, but was largely concentrated in the bones, which were not eaten. It had been stated that baking-powder might contain a considerable quantity of fluorine.

Dr. Weaver described certain dental investigations in five-year-old and twelve-year-old children in North Shields and South Shields. North Shields water had a fluorine concentration of less than 0.25 part per million, but in South Shields water the concentration was 1.4 parts. The investigation showed that there was a lower incidence of dental caries in South Shields, but the most important lesson to be drawn was that the inhibitory property of fluorine was of rather short duration. At first sight it might seem that caries was inhibited by nearly 50%, but actually the effect was only to postpone the onset of caries for from three to five years. A question which might be put was that if the incidence of dental caries at certain ages in South Shields was so much less than in North Shields, and dental disease was inimical to health, was there any evidence that the South Shields child population was healthier than

that of North Shields? There was no striking difference between the two towns in this respect, and it was evident that only a limited beneficial effect might be expected from fluorine in drinking-water.

Something must be said about the possibility of fluorine doing harm. A good deal had been written about the toxicology of fluorine, in particular that it caused hypercalcification of bone, and that in fluorine districts goitre was specially prevalent, though he had not found this in north-east Durham. There was no doubt that fluorine was a toxic substance and would do harm if taken in considerable quantities, but there was no evidence that, apart from the unsightly appearance of the teeth, there would be any ill effect from the prolonged ingestion of water containing not excessive amounts of fluorine.

Was the effect produced during the pre-eruptive or the post-eruptive life of the teeth? Would the incorporation in the forming enamel of quite a small amount of fluorine render the enamel more resistant to caries? Laboratory experiments had been carried out, but it was doubtful whether reliable conclusions could be drawn from experiments *in vitro*. From an examination of several hundreds of children he had come to the conclusion that it did not matter whether the child's residence in a fluorine area had been long or short—or, to put it in another way, so far as the six-year molars were concerned it did not seem to make any difference at what period the child had come to live in the fluorine area—provided he arrived there before the age of 6. It seemed to be essential that the child should have ingested fluorine for a period, even if only a brief one, before the eruption of the six-year molars. Children over 6 when arriving in the area appeared to derive no benefit at all so far as the protection of their six-year molars was concerned. If the fluorine conveyed any protection in the post-eruptive stage it was only during a short period following eruption. Protection was acquired during the late stage in the pre-eruptive life of the teeth, but the acquirement of such protection just after eruption could not be ruled out.

In some places in the United States and Canada fluorine was being added to drinking-water in order to study the effect on dental caries, but such a method was not one to be adopted without serious consideration, and for his own part he had never suggested that the fluorine content of drinking-water should be raised above one part in a million.

In discussion it was argued that the degree of mottling found when there was a certain amount of fluorine in the drinking-water was conditional upon the state of nutrition of the teeth. This had been shown in investigations in Italy and Morocco. Arab children in Morocco who were badly nourished showed mottling conspicuously, while French children in Morocco who drank the same water had teeth of normal appearance. Dr. Weaver pointed out, however, that there were other factors to be considered. It was not only a question of the amount of fluorine in the water but of the amount of water which was drunk.

PATHOLOGY OF RECTAL CANCER

THIRD LETTSOMIAN LECTURE

In his third and concluding Lettsomian lecture, delivered before the Medical Society of London on March 1, Dr. CUTHBERT DUKES dealt with the special problems of rectal cancer.

The records of St. Mark's Hospital, he said, proved that in rectal cancer biopsy was a trustworthy procedure. Between 1930 and 1945, 2,118 biopsies were carried out preparatory to excision of the rectum; in each case a comparison was made later between the original biopsy diagnosis and the tumour subsequently removed, and in all but 17 cases there was agreement. In 15 of the 17 the biopsy report had been "villous papilloma," whereas operation showed the growth to be carcinoma. These were all examples of a carcinoma developing in a villous papilloma, and it so happened that the biopsy fragment included only the villous portion.

Operation Specimens

Haemorrhoidal rectal cancers were divided into two varieties: adenocarcinoma and colloid carcinoma, the latter term being

used to describe tumours the individual cells of which were distended with mucus, giving a signet-ring appearance. mucoid material was found only in the lumen of the acini the tumour was described as an adenocarcinoma undergoing mucoid degeneration. Adenocarcinoma was much the commoner of the two varieties, and might be subdivided according to the histological grade of malignancy into low-grade, well-differentiated tumours, average grade, and high-grade, neoplastic tumours. Tumours might be confined to the rectum or spreading into the peri-rectal tissues. At St. Mark's classification had been adopted, which recognized four stages in the process of the disease: growth limited to the rectum; growth spreading by direct continuity into adjoining structures but not yet giving rise to lymphatic metastases; further spread with lymphatic metastases; and beyond the scope of surgical care. Judging from operation specimens the growth was still at the first stage in about 15% of cases operated on at the second stage in 35%, and at the third stage in 50%. Success or failure in surgical treatment depended largely on the extent of lymphatic spread, and account should be taken of all possible paths of lymphatic spread when planning an operation.

The lecturer gave an account of the pioneer work of the late Ernest Miles. It was now well established that the first glands to receive metastases in rectal cancer were almost invariably those lying close to the primary tumour. After this the superior haemorrhoidal glands were usually invaded in sequence from below upwards, so that in an advanced case of cancer of the lower third or ampulla, metastases came to form an unbroken chain extending from the regional group of glands to those situated at the point of ligature of the inferior mesenteric vessels. In the upper third of the rectum and recto-sigmoid region the first direction of lymphatic spread was also upward, and it was rare to find any metastases in glands below the primary tumour, though this might sometimes occur if the upward path of spread had been blocked. Downward spread of this character was exceedingly rare. The follow-up record at St. Mark's showed that prognosis after excision of the rectum depended very much on the extent of the lymphatic involvement. A generalization which it was easy to remember was that patients with more than five metastases rarely lived for five years.

When operation specimens of rectal cancer were dissected, evidence of extensions within the haemorrhoidal veins might be found in about 15% of all cases, usually taking the form of a solid cord detectable by palpation and extending only a short distance. In most cases the growth within the veins preserved its continuity with the primary tumour, and was more than a special form of direct local extension. It was as if the malignant tumour, having found the path of least resistance, had pushed a root-like process along the lumen of the vein. Occasionally a massive permeation of the haemorrhoidal veins accompanied by thrombosis was found. The evidence of venous spread was most often found in anaplastic varieties of carcinoma. It was present in more than 30% of tumours reported as high-grade, but in less than 3% of those of low-grade malignancy. The finding of clumps of cancer cells within one of the haemorrhoidal veins made it more likely, though did not definitely prove—that spread to the liver had occurred. There was no doubt that concealed and unsuspected hepatic metastases accounted for most of the unexplained deaths in the first year or two after excision of the rectum. Rectal hepatic metastases might also lie dormant causing no symptoms for five years or longer.

Choice of Operation

Surgery was still the only form of treatment which offered any hope of permanent cure in rectal cancer. Dr. Dukes discussed the operations in most general use—perineal excision and combined abdomino-perineal excision, with the recent variant, synchronous combined excision, in which two operations worked together, one from above and one from below. At the moment there was a revival of interest in all surgical procedures which sought to avoid a permanent colostomy and to preserve the anal sphincter.

In order to decide whether more use could be made of these restorative operations he had reviewed the pathological records of a large series of cases treated by combined excision, finding

ascertain whether, had all the facts been known, a restorative operation might have been employed instead. Certainly some cases treated by combined excision might have been equally well treated by restorative resection so far as pathological considerations were concerned, but on the other hand pathological findings were often present which might adversely affect the prospects of cure by restorative procedures. His own view was that the wave of enthusiasm to remove a carcinoma of the rectum or recto-sigmoid by methods which would obviate colostomy needed to be kept in check. Only experience could show whether this new development of rectal surgery could give as satisfactory results as the older well-tried operative procedures.

End-results of Surgical Treatment

Dr. Dukes proceeded to give the end-results of surgical treatment of rectal cancer as afforded by the records of St. Mark's Hospital. About half the patients who survived the operation of excision of the rectum were alive after five years, a very satisfactory result in view of the fact that the surgeons at the hospital all adopted a bold policy towards rectal cancer and their operability rate was more than 80%. This analysis was based on 716 cases treated by radical excision between 1928 and 1941 inclusive. Only 12 of the 716 cases had not been cured for five years, and these uncured cases were regarded as having died. In these calculations no distinction had been made between deaths due to recurrence and those due to other causes. By making an estimate of patients who might be expected to have died from other causes during the five-year period, and allowing for this, an approximate figure could be arrived at for the number of patients actually "cured," namely, 31.1%. The "cure rate" figure was thus slightly more favourable than the survival rate.

Of the 716 patients, 337, or 47.1%, were alive after five years. Approximately half these patients were treated by the perineal and half by the combined operation. The five-year survival rate of patients in whom the tumour was limited to the rectum was 81.9%, and only 62.3% for those with extra-rectal spread even though no metastases were present. For cases without lymphatic metastases the rate was 68.1%, whereas for those with such metastases it was only 26.2%. The unfavourable effect of lymphatic metastases was demonstrated especially after perineal operations. For patients without lymphatic metastases the difference between the two operations was insignificant, but for those with lymphatic metastases the five-year survival rate after perineal excision was only 17.4%, whereas it was 33.3% after the combined operation. The reason for this was because metastases in the upper haemorrhoidal glands might be removed by a combined though not by a perineal excision.

The histological grading of tumours was also of value in relation to prognosis, though less easy to define. The five-year survival rate worked out approximately at 60% for low-grade, 30% for average grade, and less than 30% for high-grade or anaplastic tumours. Metastases were found with only 18.4% of tumours classified as of low-grade, but with 78.2% of those of high-grade malignancy.

What sort of life did the five-year survivors lead? Dr. Dukes said that recently he had the opportunity of visiting 100 ex-patients from St. Mark's in their homes. All of them had had the operation of excision of the rectum for cancer, some only a few months, others several years, previously. His purpose was to collect information about the management of a colostomy, but he made notes of other matters also. Nearly all the ex-patients were in good health; eight or nine were semi-invalids, only two were bedridden. Most of them were over 50 years of age, and their general health seemed as good as one would expect to find in any similar group of elderly people. Nearly all could do some sort of work, usually household duties; only five complained that they could do nothing, and only one said he wished he were dead. Most of them spoke more of the kindness and help they had received from others than of their own troubles, and all referred with great gratitude to the skill of their surgeons and the solicitude of the nursing staff. He thought it true to say that nearly all these 100 survivors were glad to be alive, and they were less handicapped by colostomy than one would have supposed.

CONSTRUCTIVE PERICARDITIS

At a meeting of the Liverpool Medical Institution on Feb. 5, with Mr. BRYAN L. MCFARLAND, vice-president, in the chair, Mr. F. RONALD EDWARDS read a paper on tuberculous pericarditis and constrictive pericarditis.

Mr. Edwards said the object of his paper was to stress the relationship between tuberculosis and constrictive pericarditis. Four cases of subacute tuberculous pericarditis had been operated upon, as had six cases of chronic constrictive pericarditis which he described. In the chronic group there had been a history of pleurisy some five to twenty-five years previously, similar to that in the subacute group. He believed that cases of chronic constrictive pericarditis with calcification were the residuum of a much larger group of cases of so-called cardiac failure, some of which might have been saved by cardiac decompression. The paper was illustrated by a colour film showing the operative technique.

In the discussion which followed Mr. HUGH REID said that he preferred a postero-lateral transpleural approach to the pericardium, removing the eighth rib on the left side. This was simpler to perform, left no defect in the chest wall afterwards, and gave ample access to the ventricles and the apex of the heart. The only objection was a temporary embarrassment of respiration while the patient was being fixed on the table. Mr. Reid then showed one of his cases, a man aged 20 recently operated on at the Royal Infirmary.

Dr. T. CECIL GRAY said that anaesthesia in cases of constrictive pericarditis presented certain problems. These patients always had a poor myocardial reserve. They might also have ascites and some pleural effusion. The margin of safety was extremely small until the pericardium had been released, when the change in the patient's condition was often dramatic. This small margin of safety was well shown by the cyanosis which might occur purely through putting the patient in the lateral position for thoracotomy. Both he and Dr. Halton were very convinced of the real danger of the use of intravenous barbiturates in these cases, but in adequate dilution, for example, 2.5% thiopentone, and in small doses—of the order of 3-4 ml.—they could be used for induction. It was advisable, however, to allow the patient to breathe oxygen both before and throughout the injection. The anaesthesia was then deepened with cyclopropane and oxygen and an endotracheal tube inserted. Anaesthesia was maintained with ether in the closed circuit in preference to cyclopropane, because the latter had often been found to cause severe degrees of cardiac arrhythmia during any dissection around the heart. There was no definite contra-indication to the use of small doses of tubocurarine to aid induction and reduce the amount of anaesthetic required provided that adequate ventilation was maintained with oxygen.

Dr. E. L. RUBIN drew attention to the site of pericardial calcification which most commonly covered the under and anterior surfaces of the right ventricle and most rarely the left auricle. Neither pericardial calcification nor the absence of radiologically visible pulsation necessarily implied constriction and both were occasionally encountered in patients who were without symptoms or other signs. An exaggerated auricular impression on the oesophagus similar to that seen in mitral stenosis was sometimes encountered, due not to enlargement of the left auricle but to thickening of the pericardium.

At the same meeting Dr. GODFREY BAMBER read a paper on some defence mechanisms of the skin.

At a clinical meeting of the Medical Society of the L.C.C. Service held at Hackney Hospital on Feb. 5, Mr. J. Gillies showed cases of various renal anomalies. Dr. Cardno described a case of sixth nerve palsy in a man of 77 following low spinal analgesia with complete recovery in eleven weeks. Mr. Jamieson showed four cases of tumours arising in sebaceous glands, two innocent and two malignant, and said that he considered them all examples of "Cock's peculiar tumour."

Local authorities have found it difficult to provide suitable accommodation for midwives, district nurses, and health visitors. A circular from the Ministry of Health asks that the utmost possible assistance may be given to finding suitable accommodation for them.

Correspondence

The Colleges and the Act

SIR.—The crisis which now faces British Medicine calls for high and courageous thought. The plebiscite revealed the unity of the profession, a unity which springs from a complete distrust of the absolute power given to the Minister and the conversion of Medicine into a State monopoly. The profession is convinced that in opposing service it is acting in the interests of freedom and of the public and that it is safeguarding its own precious heritage.

A situation has arisen in which the B.M.A. has had to assume leadership. Certain professional observations are, however, called for. The action of the Presidents of the three Royal Colleges in January, 1947, was a risky one and it failed in its object. It damaged the prestige of the Colleges, endangered relations between consultants and general practitioners, encouraged the Minister, and misled the Press. The B.M.A. represents primarily the general practitioners, and there has never been any doubt about their attitude to the Act. Consultant opinion was not equally well represented on the Negotiating Committee, as the Colleges are represented in their corporate capacities and not by delegation from their Fellows. In the case of the largest College—the Royal College of Surgeons of England, with some 2,600 Fellows—the President and Council did not obtain the direct views of the Fellows, and no meeting of Fellows has been held since Nov. 29, 1946. And in a crisis such as the present one the leaders must derive their moral authority from their Fellows as the B.M.A. does from the Representative Body.

The Presidents had two primary obligations to the profession: first, to make clear the principles upon which the Act was based; and secondly to give their opinion as to the importance they attached to the heritage of freedom in the practice of medicine. They did neither of these. In consequence, consultants were demoralized and slow to realize the implications of an Act which places them at the mercy of a State monopoly.

A forgetfulness of Lord Halifax's maxim that "State business is a cruel Trade: Good-nature is a Bungler in it" is one of the reasons for our present troubles. Coalition governments are maintained by hard bargaining, and in the dark days of the war a hard bargain was struck which pledged social security and implied the nationalization of medicine. The repercussions of that bargain are now evident. Such a bargain explains the similarity of the health policy of all the political parties and the schemes of the successive Health Ministers, and it also explains the unwillingness of the Presidents to give clear leadership to the profession. Doctors are responsible and reasonably well-behaved citizens, and they will not break the law if they do not agree to serve under the Act, since their deepest convictions are that the Act will be disastrous in its effect.

I have never thought the Act capable of amendment which would lead to improved medical services and medical education and yet maintain that freedom which is vital to the practice of medicine. The interests of the public and the interests of the profession both call for the repeal or abandonment of this Act. The objections in principle are to the absolute Ministerial power, the creation of monopoly, and the certainty of political control. The practical objections are also weighty. We shall never trust Mr. Bevan, and it will take many years to restore our confidence in the intentions of any Minister of Health. The Minister and the Act have destroyed our good will, so that if the Act ever operates it will be with the same material resources but with fewer medical men and without the good will and confidence which alone make medicine possible. The sick public will suffer. The capital expenditure envisaged under the Act cannot be incurred, and an economic blizzard may aggravate the disorder of the health services and bring chaos and confusion. If the Act is forced on the community against the expert advice of the doctors, then the Government must accept responsibility.

In the events leading up to the present situation many have played a part—the B.M.A., the Royal Colleges, the Government, but especially the politicians, who have exploited the medical profession in an endeavour to attract votes. The situation

calls for all available political and medical leadership. The abandonment of the present destructive Act will be a first step in construction. Both political theory and grandiose planning will have to be forsaken if they are not to disorganize medical institutions, traditions, and confidence, and if that sense of vocation is to remain in work which is as private and intimate as the care of the sick. In the *Journal* of January 18, 1947 (p. 102), I wrote: "We are members of a free and liberal profession. I want that freedom to continue as one of the freedoms of a democratic community. As healers of the sick we shall continue to give our best if free from State coercion." That is still our faith.—I am, etc.,

London, W.1.

REGINALD T. PAYNE.

No Health Centres

SIR.—Mr. Bevan's irresponsibility is glaringly illustrated in a Parliamentary answer he has given me (Feb. 10), which I append (see *Journal* of Feb. 28, p. 421). It is not too much to say that the health services under the N.H.S. Act were to be provided in predominant measure by the machinery of the health centres; a glance at Section 21 of the Act proves this contention. In Mr. Bevan's own words they were to be "the key feature in the general reconstruction of the country's health services." But without any notice to the medical profession and almost clandestinely, the Minister announced in Circular J 1948, on Jan. 14, that because of the building situation provision of health centres must be postponed indefinitely. Still more certain must be the indefinite postponement of any new provision of hospital accommodation, or even any attempt at restoration of the buildings destroyed at the great London hospitals by enemy action.

Circular 3, 1948, gives a further revelation of irresponsibility. In paragraph 5 the Minister shows that he is completely in the dark as to what the health centres should provide, and he proposes to set up a "special committee to gather information as to the aim to be pursued, and he stresses the need "for intensive research and thought about the design before the new development is launched."

The provision of institutional and specialist treatment was one of the most attractive promises of the Act and indeed perhaps one of the strongest single influences in securing its passage. But the Minister in answer to me on Feb. 10 calmly informed the House that "no immediate substantial increase of the building work under the Act has ever been promised or regarded as feasible." The Act is to be put into operation within the next four months in the total absence of any possibility of fulfilling undertakings whose execution depended on provisions now indefinitely postponed. In a recent broadcast widely reported Dr. Stephen Taylor, M.P. (who constantly assumes the rôle of mouthpiece for the Minister), gave an "absolute assurance" that the Act would come into operation on July 5 with whatever resources of staffing might then be available, even though the might not cover more than half or even a third of the population, but no suggestion was offered as to how the population not so covered is to obtain medical attention after the elimination of the existing N.H.I. services. It seems clear that the unfortunate patients not included in the half or third covered will be required to pay the full levy, even though they receive none of the benefits or services in respect of which the levy is made.—I am, etc.,

House of Commons.

E. GRAHAM-LITTLE

The Political Perspective

SIR.—As you stated in the first leading article in the *Journal* of Feb. 21 (p. 347) the result of the plebiscite has placed heavy responsibility on the B.M.A. and especially on the forthcoming Special Representative Meeting on March 17. It is important to realize that this responsibility is of a new and important kind. The recent debate in Parliament has shown that the issue now regarded very much as a political one. It is most regrettable that politics and medicine should be so mixed up that they be temporarily identified, and it is also unfortunate that, as stated in the debate, doctors are seldom good politicians. (Perhaps this is because they have learned care in diagnosis, humility in prognosis, and moderation in statement.) It is therefore, that the matter should be seen in its political background, which should surely be present in the minds of all

meet on March 17, I should like to recapitulate some recent events which in their sequence and consequence seem to throw some light on the political perspective.

Towards the end of last year it was being rumoured that Britain's place in the Marshall queue might be very low, alarmingly so if the present Socialist policy were to be completed. It was therefore essential to make a bid for a higher place, and this was done by Mr. Attlee's speech on Jan. 3 roundly condemning Communism and emphasizing freedom, thereby pleasing America but disgruntling his left-wing supporters. These needed to be placated if the façade of harmony were to be maintained, so the device, unique in our history, of giving a vote of confidence to a Minister who had not been attacked was devised. The plebiscite was made the occasion for this demonstration of confidence in Mr. Bevan, the leader of the left-wingers, and careful reading of *Hansard* shows how successfully and exactly it was carried out, with a mastery of technique to satisfy Hitler himself.

Parliament was asked to say that it was "satisfied that the conditions under which all the professions concerned are invited to participate are generous and fully in accord with their traditional freedom and dignity"—when in fact the financial conditions for consultants, etc., are unknown, so that apart from a blind faith in Mr. Bevan no one could say whether they will be generous or not, while the regulations which will determine whether the conditions for most doctors are compatible with their "freedom and dignity" are also largely unknown.

Mr. Bevan, having said that "so much misrepresentation has been engaged in by the B.M.A., etc." then went on to misrepresent completely his discussions with the Negotiating Committee for the past year, for no one could gather from his speech that this time the "Negotiating Committee" had no power to negotiate but only to discuss and report back. This misrepresentation obviously convinced many members of the unreasonableness and intransigence of the doctors and coloured the whole debate.

The crowning achievement was of course to represent "the will of Parliament" as supreme not merely in matters of administration but in the sphere of morals and conscience as well (more will be heard of this later). This occurred because most of the members could not discern behind the specific objections of the Negotiating Committee the issue of professional freedom and duty to one's patients.

While doctors are not free from blame in this result, the debate made it clear that this Parliament is not versed in the art of discussing freedom in the dialectic of finance and regulations and was genuinely bewildered by the ostensible purpose of the debate, but it was a brilliant success in soft-soaping Mr. Bevan and his followers and in sweetening the bitter pill they were to swallow the next day when the Government issued the White Paper on the stabilization of wages, etc. All this goes to show how carefully the matter was timed and what importance the Government attached to making the doctors into a whipping-boy to please their extremists. No one can say that it does any good for the projected Health Service, either patients or employees, but it does emphasize the extreme seriousness with which we should meet on the 17th and the need to weigh even more carefully than usual what we say and the way we say it.

In the leading article in the *Journal* of Feb. 28 you stress the importance of public opinion, so I trust that this time the proceedings of the S.R.M. will be in public and that speakers will be the opportunity to make crystal clear to the wider public exactly what it is we are fighting for—how easy to say and to tend, but how difficult to do!—for at present public opinion is as confused and ill-informed as was Parliament a few weeks ago. We must emphasize the danger to clinical freedom, development, and research inherent in the Treasury control at the Act lays down for the Service, and show what it may mean for our patients. Enough is already known of some regulations to show what a mockery they may make of Mr. Bevan's promises about clinical freedom and doctor-patient relationship.

One would think that the dangers of a monopoly are already sufficiently known, or at least professed, to need no stressing, but this is not so. In fact most people seem to be unaware at the struggle between the doctors and the Act is really the attempt to maintain freedom in an ordered service, only

this time it will touch every individual in the most intimate parts of their physical, mental, and even moral existence. So far no satisfactory solution of this difficult problem has been found, but few solutions are so obviously bad as that proposed in the Act, which gives almost absolute power to the Minister and trusts that his promises of freedom (which the Treasury has power to nullify) will be kept.

Even if Mr. Bevan does his best, it is obvious that the Act is an instrument ideally formed for a dictator, and if the doctors accept it as it is they will have taken a long step for themselves and for their patients on the road that leads to Prague, or perhaps it will be Helsinki by this time next week. I believe that this is the crucial issue, and if we can make the people see it I have no doubt as to what their opinion will be, and even Parliament may have to admit that "the will of Parliament" ought to express the will of the people, as it certainly ought to seek their good, which is after all what we doctors exist to defend and to serve.—I am, etc.,

Winsted, Cheshire.

W. N. LEAK.

The Paternal State

SIR.—Dr. G. C. Pether (Feb. 28, p. 411) has raised the important question of the potentially deleterious effects of undue control by the State and extensive plans for "social security" on the development of the individual personality. It is not altogether true, however, that "psychologists have paid so little attention to the cramping and thwarting of personality" inherent in such trends. On the contrary, there has been for many years among eminent psychologists and psychiatrists a remarkable consensus of opinion as to the psychological significance and dangers of an over-protective and authoritarian "paternal" State, and as to the relationship between emotional and social maturity of the individual and a liberal democratic form of society.

The conclusions reached as early as 1921 by J. C. Flugel in *The Psycho-Analytic Study of the Family* (London) to-day seem as prophetic as they are relevant:

It is fairly clear that there exists a tendency to resurrect some of the parental attributes and give them a political application by bestowing them upon the State. The world war has taught us the necessity of implicit obedience to the State and its representatives—military and civil; the right of independent thought, action and criticism being to a large extent suspended and the minute details of our lives being subject to order and inspection in much the same way as in our childhood they were subject to the supervision of our parents. Again, modern socialistic thought—especially in its cruder aspects—has produced a state of mind, as a result of which the individual becomes to a large extent absolved from the responsibility for his own education, progress, and maintenance, and for those of his children. The adult individual is thus led to transfer on to the State that attitude of dependence which he originally adopted in relation to his parents. . . . If our conclusions are correct, there is a danger in too wide a ramification of State provision and State control, inasmuch as it is liable to prevent that full development of individual power, initiative and self-reliance which can only be obtained by a high degree of emancipation from the primitive attitude of dependence on the parents.

F. Alexander in *Our Age of Unreason* (1942, Philadelphia) similarly states:

Democracy must educate its members to emotional maturity if it is to survive, and psychiatry must help to develop educational methods for overcoming infantile dependence and developing responsibility.

O. H. Mowrer (*J. Soc. Psychol.*, 1939, 10, 121) writes:

Modern fascism springs from psychological roots which are as old as the human family and which are by no means confined to the populace of those countries in which fascism has gained official status. The danger of emergence and growth of such a political doctrine, with its emphasis upon subservience and blind submission . . . comes, not from propaganda and pressures from outside, but from a country's own internal educational and economic institutions. No one, I believe, can at present point with certainty to the solution of this important problem; but surely encouragement of greater independence and emotional self-sufficiency in children . . . is a step in the right direction.

It would appear then that superficial methods of education designed to mass-produce men and women according to a preconceived "average" pattern, or which would regard all

children as identical or potentially "equal" in their capacities, should be avoided at all cost if we wish to preserve our democratic way of life. On the basis of his study of human constitutional types W. H. Sheldon (*The Varieties of Human Physique*, 1940, New York) was led to the conclusion that "children of different constitutional components probably need different educational influences, just as trees which lean in different directions need to be supported from different angles." This "differential education," as he termed it, necessitates the conception of education as "an effort to discover and develop the peculiar potentialities of the individual, more or less regardless of the immediate social value of the emerging traits. The assumption is that the aim of life is not social adaptation and conformity, but maximum individual development."

Finally, one of the most profound thinkers of modern times and one who has made invaluable contributions to psychiatry, C. G. Jung, in his *Essays on Contemporary Events* (1947, London) has recently written :

The parental imago can now be projected on to the State as the universal provider and the authority determining all thinking and willing. The natural development of the soul is no longer repressed by a spiritual order of direction which bridges the centuries and keeps cultural values alive, but by a political directing order which serves the power aim of particular groups and promises the mass economic benefits. In this way the deeply rooted urge of the European towards a patriarchal and hierarchical order finds an apt and concrete expression which corresponds only too well to the interests of the masses, but which is fixed at such a level as to be in every respect detrimental to culture. . . . It is perhaps a lamentable sign of the spiritual immaturity of European man that he both needs and desires rather a large measure of authority. . . . Jung then sets out to bring everything that wants to grow to the surface of growth would soon find that the weeds, which always flourish best, had shot above his head. I therefore consider it the task of psychotherapy to-day to pursue with singleness of purpose the goal of the development of the individual.

It is well recognized that a basic standard of social and cultural maturity is essential for the emotional maturation of the individual to be possible. But it would seem from all the evidence available that it is only by educating the individual to initiative, self-reliance, and independence, giving him the opportunity to improve his own and his family's condition through his own efforts and insisting that he should, in so far as his capacities permit take upon himself the burden of his responsibilities as an adult that there can be any hope of giving rise to well-adjusted and mature personalities and a lasting and authentic culture. In the face of contemporary events and ideological trends it would be difficult indeed to find place for any such hope outside the realm of fantasy.—I am, etc.,

Censorship of Opinion

SIR.—The Council of the Society of Medical Officers of Health at its last meeting discussed the statement in your leading article entitled "Censorship" (Jan. 31, p. 202) that a county medical officer of health recently instructed the public health medical officers on his staff not to take part or vote in a meeting held in their area to discuss the National Health Service Act, and that those officers who were present had to sit in enforced silence. It was the unanimous view of the Society's Council, and of the medical officers of health and departmental medical officers from all types of local authorities, that the instruction mentioned above was neither proper nor permissible. It was a gross violation of a public health department, and of its medical officers, their disclaimer of any support for such an instruction on the freedom of opinion of the medical profession.

GEORGE F. BUCHAN,

Chairman of Council,
Society of Medical Officers of Health.

The Northern Ireland Act

It is a pity that there is some misconception concerning the provisions of the Northern Ireland Health Service Act in regard to the medical profession. The Act contains in Section 7 the provision that the medical profession shall take service under the Health Service. This does not mean that the medical profession shall be required to take service under the Health Service on the appointed day and

thus lose the right to sell the goodwill of their practices. These provisions have been inserted in agreement with the representatives of the medical profession in Northern Ireland, the negotiations having been conducted with the Northern Ireland Branch of the British Medical Association.—I am, etc.,

London, S.W.1.

W. BROOKE PURDON.

* It may be useful to summarize the main features of the Northern Ireland Act. The hospitals will not lose their endowments ; there is a right of appeal to the courts ; the capitation method of remunerating general practitioners is laid down in the Act ; there are no penal clauses ; there is no negative direction or control. The doctors agreed to the abolition of buying and selling on the understanding that if this provision were removed from the English Act a similar course would be taken in Northern Ireland.—Ed., B.M.J.

The Fight for Freedom

SIR.—It was with a deep and sincere feeling of elation that I read the letter by Dr. A. C. E. Breach (Feb. 28, p. 412). I fully agree with him that the medical profession is surely now the last and only hope of true freedom. We must be ready and willing to fight, not just for ourselves against a dangerous Parliamentary Act, but we now have to regard ourselves as "commandoes of the public." If we fail in our fight, and we can only fail through cowardice and personal greed, we will be regarded by the public as a "very poor lot," whereas if we are the first in this country to take up our positions against tyranny not only will we ourselves feel happy in doing what is our honourable duty, but truly it may be said many years hence, "The doctors showed the British people strength, honour, and the road of the way back to greatness, and the British people took that road, and when they eventually rested they were indeed great."—I am, etc.,

Liverpool.

A. E. BERNSTEN.

Association of Rural General Practitioners

SIR.—I should like to support Dr. O. F. Conoley's letter (Feb. 7, p. 273) on rural mileage and practice expenses under any new Service. Living five miles from the nearest small town and eleven from any big town, one is forced to keep two cars. As both are nine years old they take turns in being repaired. Up till now, private practice has paid for purchase and upkeep ; panel mileage allowance has covered merely tax and insurance of one car, therefore panel patients are almost entirely subsidized by private ones.

Something should be done about the initial two-mile limit before payment of any allowance. Ten roads radiate from my village. I can easily do forty miles in any morning, seeing to panel patients at the two-mile limit on each road, and get precisely nothing for my travelling expenses. When private practice no longer exists that is just what will happen.—I am, etc.,

Kemerton, Glos.

D. M. WILKINSON.

Radical Alteration Required

SIR.—It is time for a wider recognition of the fact that the present National Health Service Act is not directed to medical reform but to political ends and to bureaucratic expediency. For if the Government had been actuated solely by the desire to improve the medical services of the country another and more effective plan, easier to draft and to apply, and less subversive of the good features of English medicine, would have been produced. Men of good will, in whatever Party they may be found, should combine with the profession (which alone has so far shown good will) to urge upon the Government the desirability of a radical alteration of the Act. Nothing less will secure a contented profession and, through it, a satisfied public. For it is upon the freedom of medicine that many of the advances in the past have been built, and there is no reason to suppose that the revolution in progress at present will effect any change in that respect.

Failing the complete redrafting of the Act, which was passed by a Parliament inadequately advised by the profession, there are certain amendments which, if made, could go a long way to preserving the freedom which we, as doctors, regard as essential.

1. A previous letter in the *Journal* has shown the way in which the objectionable "universal basic salary" could be made harmless by converting it into an expenses allowance.

terms of tonic value

The value of a tonic cannot be measured in simple numerical units. But desiderata for such a preparation can be placed under well-defined functional headings: *restoration, formation and protection.* Syrup Minadex is well equipped to fulfill these functions. Iron, calcium, and other minerals comprise the stimulatory and formative elements of Minadex. The vitamins A & D of Minadex are specific in a protective sense. Combined in an orange-flavoured syrup enjoyable to even the most fastidious patient, these factors restore lost appetite and hasten the return to full health.

In 6 oz. and 12 oz. bottles.

Each fluid ounce contains: Vitamin A 18,000 i. u. Vitamin D 2,000 i. u. Iron and ammonium citrate 13½ grains. Calcium glycerophosphate 2 grains; other minerals.

Vitamin Therapy -its uses and limitations

SUB-FERTILITY,

while demanding the fullest investigation if treatment is to be successful, may resolve itself into a need for full supplies of the dietary factors concerned in reproduction. Of these, the natural forms of vitamin E, present in whole wheat germ oil, are known to be of the first importance.

FERTILOIL

is stabilised and standardised wheat germ oil containing 3 mg. vitamin E per capsule. One to three capsules daily suffice for most cases. The vitamin is best utilised when given by mouth and treatment should in most cases be continued for several months. In pregnancy, the earlier treatment is begun the better.

SULPHONA-CREAM

In order that the doctor may have a free choice of bacteriostatic dressings, **SULPHONA-CREAM** is now offered to the medical profession.

SULPHONA-CREAM can be used as an ointment, or applied on a sterile spreader direct to a diseased or injured area, or spread on gauze, linen, or oiled silk.

The formula is the same as that used for the emulsion in **SULPHONA-TABLETS**—suitable only on prescription—has been continued unchanged in the past years due to its acceptance and approval by doctors as a product based on the latest scientific knowledge.

SULPHONA-CREAM is indicated in the treatment of burns and as a primary dressing to prevent infection. It is also successful in the treatment of septic skin lesions of indolent ulcers, and for burns and septic infection has already occurred. The dressing when used in conjunction with **SULPHONA-CREAM** need only be changed at intervals and healing proceeds rapidly without disturbance of the superficial tissues.

SULPHONA-CREAM is sold in tubes and is thus maintained in a sterile condition. The sterility and composition of each batch is checked by physical, chemical and chemical examination.

Each tube of **SULPHONA-CREAM** contains 10% w/w Sulphanilamide in a sterile emulsion.

10 tubes in 15 open boxes, 1 tube in 15—each.

Special prices for hospital quantities.

2. The ban on the sale and purchase of practices could easily be replaced by a State power to buy practices, or shares in practices, at their market value when vacancies occur. By this means there would be no bar to the entry into practice of any man who could not afford to purchase one, for the State would buy his practice for him and install him as the tenant. The transfer of goodwill of practices to the State would thus be a gradual process instead of the upheaval that the Act demands. This method would also remove the offensive "big stick" of the restrictions on payment of compensation with which the present Minister hopes to bludgeon the profession into acceptance.

3. Mr. Bevan is in error in saying that the recent law allowing the right to sue the Crown will provide all the appeal against a Ministerial decision of dismissal that the profession could require. Mr. Bevan in the House made great play with the fact that the doctor would have the right of appeal against unlawful dismissal. Maybe, but the profession requires the right of appeal against unfair dismissal.

4. The right of the profession to put its elected representatives upon all the governing bodies of the Service could well be conceded without harm to Ministerial control and with enormous advantage to the Service. As at present planned, the Service will be run by the Minister, the Civil Servant, the administrative medical officer, and the local authority; the last person to have any power will be the doctor, who actually does the work.

—I am, etc.,

Portsmouth.

NIGEL CRIDLAND.

Some Alternative Suggestions

SIR,—In your leading article of Feb. 28 (p. 397) you state: "The medical profession and the Minister of Health have one important end in common and that is to provide an efficient medical service for the people of this country." You then continue to write about the adjustments necessary to the Act in its present form. These two statements are irreconcilable, as no adjustments of the Act can possibly improve the service of medicine to the public, although they may mitigate several potential dangers. The Act as it now stands sets out to do two things. One is to provide a "free" service, and the other is to control the profession. I cannot believe that there was any intention to try and improve the service of medicine or it would surely have shown itself somewhere. Yet if a great reform of this kind is initiated it should have as its basis an aspiration to improvement in all its spheres.

What are the hindrances which are holding back the profession? They are first the fact that all G.P.s are grossly overworked and cannot give the time they would like to each patient, and secondly that out-patient and in-patient accommodation in hospitals is seriously inadequate. The latter is a question of building and of nurses rather than of medical staffing and cannot be solved in the immediate future, but could be alleviated if the former were rectified. If G.P.s' surgeries were not so crowded, then it is possible that fewer cases would find their way to the out-patient department. If G.P.s' rounds were not so rushed, then they would feel more able to cope with minor serious medical cases which otherwise would be sent into hospital.

It would therefore seem that if G.P.s' practices could be limited in size, then most of the hindrances to an efficient service would be dissolved. The number of G.P.s is approximately 20,500 and the population about 48,000,000—i.e., about 2,146 per doctor. A practice of this size should be managed efficiently and without overworking the doctor. In order to limit practices to this size it would be necessary to leave out of the scheme a certain percentage of the population, because there are the less densely populated country districts with relatively small practices, and elderly and semi-retired doctors who would not attempt to see as many patients. The obvious solution would seem to be to leave out the upper-income groups, many of whom would not in any case take advantage of the Service—say, all those with incomes above £1,000 a year. The remainder of the population would therefore come under the Health Scheme and obtain free doctoring, but as the upper income groups will have to pay for the scheme then it is only just and proper that they should obtain certain benefits from it.

These criteria could be satisfied by limiting doctors' practices either by a generous capitation fee, such as 25s. to 27s. 6d. per head with a number not to exceed 2,750, or by a staggered capitation fee, such as 30s. per head for the first 1,000, 20s. for the next 500, 15s. up to 2,000, and any further patients at 7s. 6d. per head. Confinements, mileage, and the very much reduced amount of private practice would ensure standards approximating to those recommended by the Spens Report. Those with incomes above the limit should be helped by free pathological and radiological

investigations, which should be available to all G.P.s without reference to the out-patient department of the hospital.

Consultants and specialists would therefore carry on with a reduced private practice, which would entail that they should be remunerated for their hospital services. State aid to the voluntary hospitals is essential if they are to survive in this present era. If consultants and specialists were paid on a case basis, then they should not only be able to maintain their present rate of income but possibly manage to reduce their fees for private work, thereby increasing that work which otherwise would accumulate in the hospital departments.

Such a scheme would seem to have distinct advantages—namely (1) it would provide a fillip to medicine by enabling the G.P.s to work well without overworking; (2) it would satisfy all income groups of the public; (3) it would dilute State control by enabling a G.P. to leave the Service if he is unhappy and still be able to scratch a living outside; (4) it would help a young doctor, as his first patients would be the most remunerative and he would also benefit from the redistribution from the present bulky practices.

It does mean, of course, a new Act; and various other issues are not mentioned such as the buying and selling of practices. This custom, however, need not be insisted on, as there is no threat to the doctors' freedom. If it is to go it should be compensated for in the same way as other nationalization schemes—that is to say, by immediate reimbursement in the form of Government securities.

The scheme approximates to one produced by the Planning Committee of the B.M.A., and one possible reason it has not been elaborated may have been the desire to try for a 100% service. At the moment this ideal does not appear feasible owing to the amount of control apparently required by the State. If that control is the real object of the Government then obviously this scheme now suggested would meet with short shrift, but it will show that there is a scheme which could be worked efficiently—giving a better service immediately and one which could be extended as hospital accommodation is increased and health centres built. I am, etc.,

Plymouth

S. M. DAVIDSON.

Stand Firm on Four Points

SIR,—The general public are beginning to realize that there must be something in the doctors' case and the Press seems to think that the next move is up to the B.M.A. There are symptoms that we are expected to yield some concessions; indeed Drs. A. S. Hatch and F. H. Hunnard suggest (Feb. 28, p. 408) that we should yield on buying and selling practices and on appeal to the courts. I hope they will read and study the letter from Dr. J. Arthur Gorsky (p. 410), and also C. K. Allen's book *Law and Orders*. If they do, I feel confident that they will modify their views.

Unless we stand firm on all our four main points—for they are all interrelated—and if we yield on even one, our whole position will be turned and our freedom gone. So many people here and abroad are watching the situation and looking to us to show once again that the people of this country can be easily led but cannot be coerced. After all, when we agree to work the Act if our four main points are guaranteed we are still making great concessions and accepting much in the Act which is against B.M.A. policy and which we heartily dislike. To mention only a few, there is the undemocratic set-up of our representation on various boards and councils, the power of the Minister to suppress reports, his taking over of the hospitals, his proposed introduction of the full service when neither the necessary personnel nor the buildings exist to make its operation to the satisfaction of the public a reasonable proposition.—I am, etc.,

Southport, Lancs.

R. R. M. POFFER.

The Basic Salary

SIR,—Having now in no uncertain voice expressed our opinion of the new Health Act, we may safely, I think, venture on some constructive criticism with a view to attaining a workable compromise. Among other things I think we should take a new look at the basic salary. As at present envisaged it is a mere bond of servitude and has rightly been turned down as unworthy of a great profession for whom freedom is vital.

But need it be so? Why should it not become a reward for good service and incentive to better work? Instead of being a fixed sum it could be varied so that the man with experience would have a larger amount than the recently qualified, the man with a higher degree would be rewarded accordingly, and the

man in a difficult and sparsely populated area would be compensated in proportion. By increasing, say, every five years, it would rise promotion in the Service. The man with higher degree does not necessarily become of consultant status but should certainly be given some acknowledgment. In other words the basic salary, instead of making for mediocrity, could encourage progress and good work. Provided, therefore, that we can be assured that the basic salary does not lead to a whole-time State service, there seems to be much to be said for it, and we should not lightly turn it down without due consideration—I am, etc.,

ALFRED, JR. D. MURPHY

JOHN MALLOCH.

Inequality of Income

SIR, Almost every letter in the *Journal* is concerned with the moral issues involved in the N.H.S., but its financial clauses are left largely uncriticized. Splendid and laudable that it should be so! But most of us have to earn our living and must meet our obligations. In studying this less exalted point of view I have been impressed by the fact that financial injustice of the first magnitude appears to be inherent in the scheme as it is now proposed. Equality of remuneration, an equal charge for every patient on the doctor's list, will surely result in a grave inequality in the net receipts of practice. Thus, Dr. A works in a poor neighbourhood with "overheads" between £100 and £200 a year, his patients expecting a very few minutes of his time at each attendance (the N.H.I. has taught them to be content with that). But Dr. B, in better-class practice, may find his "overheads" three or four times as costly, while those who consult him will demand their quarter of an hour. A will do well; B will go bankrupt, unless he negatively directs himself to quit in A's fruitful field.

I raised this point at a meeting of a medical (or medico-political?) society which does not see eye to eye with the B.M.A. and was told that the matter would be of no importance in the Best of all Possible Worlds which is on its way. Dr. B would find cheap accommodation in a neighbouring slum, and if he wasted much time on individual patients others could soon be found who would not—I am, etc.,

LESTER, W. C.

G. LAUGHLIN SCOTT.

The Political Aspect

SIR, In view of the fact that the Northern Ireland Parliament is fully compromised with the doctors there, conceding the more important of their requirements, and that no prominence has been given to this in any section of the Press irrespective of its political colour, it would appear as though neither the Socialist Party, the Opposition, nor Mr. Bevan really wish the matter settled. This impression is strengthened by the recent debate in the House of Commons, which apart from a certain "artificial value" was in no way helpful.

So if the controversy reach its logical and inevitable conclusion it would in no way damage the Opposition, while the Socialist Party might find it less embarrassing to postpone the implementation of the Act, putting the responsibility for this on the medical profession, than having to explain to "organized medicine" that a substantial reduction in their pay packets is for the time being cannot be provided at present. As for the Government, they have here a clever and ambitious man who is not to be outdone in any way—I am, etc.,

GEO. McMILLAN.

Doctors who Might

... completed, the considered desires of the public are known, and the popular voice is heard. But nothing could be done without consulting the Government. Mr. Bevan states that he is not in a position to do so until July 5, and the question is whether the public will wait. Let us hope that Mr. Bevan will not delay. These are the days of the "Fifth Column" and the "Fifth Column" is not to be trusted.

The numerical strengths of these first two groups are not difficult to estimate and are sufficiently appreciated by all.

(3) There is the potential "Fifth Column" in our midst. Among those sincerely determined to refuse service under the Act there is a large group of young doctors who for financial reasons are open to economic coercion, a weapon not unknown to a certain type of politician. For example, of the thousands of doctors released from the Forces very few are earning their living at present. While under normal conditions the majority would have been absorbed into general practice, very few have been able to do so because practitioners have been naturally disinclined to accept partners owing to uncertainties based upon the proposed Service. As a result thousands of young doctors are "studying for higher degrees" and are being paid for doing so by various bodies such as the Post-graduate Federation. It is within the power of the Government to stop such payments, and these doctors wonder how long they can hold out without any money. Some have written to the various authorities requesting assurance that they will not be dismissed on July 5, but thanks to the Minister such assurance cannot be given. These doctors inadvertently constitute a potential fifth column: they number thousands. While some are determined not to join even if they have to temporarily give up medicine and work on farms, others openly admit that against their consciences they will be forced to join the Service unless some financial aid is assured them. It is probable that Mr. Bevan is well aware of the existence of the potential fifth column and of its value to his cause, and it is more than possible that its existence is not entirely accidental. The B.M.A. should now turn its attention to the danger and ensure that such doctors will not join the enemy through economic coercion.

(4) There is the public. All doctors agree that the wish of the people is paramount. Mr. Bevan states that he represents the wish of the people, but in point of fact the people have never been consulted. Furthermore, they have been misled by the politicians who have repeatedly told them they will have a "free service," and even this elementary falsehood is naturally accepted by the man-in-the-street, who is always anxious for something for nothing. By a series of equally misleading statements Mr. Bevan has got many of the public on his side. If, however, the public were told the truth about the Service they would think otherwise, and since all doctors wish to do what the public desires (in contradistinction to what Mr. Bevan says they desire) there the duty of the B.M.A. is clearly twofold. First, the B.M.A. should tell the public the truth about the projected Service. Secondly, they should then ascertain the considered wishes of the people by a survey of mass opinion and make the result known to everybody. If the public is with us it should silence Mr. Bevan. If it is against us the "battle" is over before the first shot is fired.

—I am etc.,

Sutton Green, Surrey.

JAMES T. HAROLD.

Ownership

SIR,—Judging by recent letters in the *B.M.J.* much confusion still exists on the all-important question of ownership of practice. One could safely say that if there was any general factor responsible for the majority "No" vote it was fear of a salaried State service with its attendant loss of freedom, and if this assumption is correct then it is imperative that the profession is emphatic in retaining ownership. It will clarify the cause if we consider it from various points of view.

The Government.—Socialist criteria for the necessity of nationalization are briefly (a) inefficiency, (b) exploitation. What increase of efficiency is to be expected by reason of buying out practice, and who is being exploited by the sale and purchase of practice? Many sincere Socialists have stated that the usual criteria simply do not apply to the practice of medicine. Why then does the Government risk wrecking the scheme on this point? It is because (and this applies to any government whatever its politics) the Treasury must call the tune through control of certification, etc.; it must have a tidy scheme. The Minister recognizes much more clearly than many doctors that if we accept compensation we must accept control. His reasoning on this point is logical and fair.

The Public and Press.—I am of the opinion that the public are not the slightest bit concerned about the financial transactions in the Act, and rightly so, but I am quite certain that if we go to the public and Press in sincerity of purpose and, most important of all, in unity we will have their support. The result of the plebiscite has won us tremendous support, and therefore let us make it quite clear why we voted.

The Profession.—Of the minority that voted "Yes" I have nothing to say, but there are many in the profession who state

to lose compensation. It is beyond my simple understanding to appreciate that people exist who imagine they can accept compensation and still continue to enjoy the freedom of medicine as at present. The price of compensation is control—a fair bargain if we accept it. It would be better if these "wafflers" stated outright that compensation relieved their moral fears and voted "Yes" to the Act now. If the Minister wins his battle of nerves it can only be through this section of the profession. Can anyone seriously doubt who will eventually win if 80% of the profession say "No"? We can scarcely expect the public to support this "have our cake and eat it" policy of this section of the profession. I cannot think of nor have I read of any substitute for the ownership of practice that can safeguard us, and it is for the profession to face this issue of compensation or control now lest we lose the confidence of our patients and the key to our freedom.—I am, etc.,

Sheffield.

ANDREW STEPHEN.

Protection of Doctor and Patient

SIR.—The profession, having denounced in no uncertain manner in the plebiscite the N.H.S. Act as at present constituted, it appears to me to be very desirable that they should formulate conditions under which they would be willing to participate in a scheme, the granting of such conditions being considered as a *sine qua non* by the profession before acceptance.

I enumerate below what in the light of 28 years' experience appear to me to be very necessary conditions for the protection both of patient and doctor in any State scheme.

(1) The right of a doctor to retain the goodwill of his own practice and to dispose of it as he thinks fit.

(2) No outside interference with the doctor-patient relationship.

(3) The right of any patient to change his or her doctor, and the right of any doctor to have a patient removed from his list.

(4) No increase in free certification beyond the limits imposed in the present N.H.I. regulations.

(5) The retention by practitioners of their present panel lists after July, and the addition to these lists of patients desiring to join the State scheme. This is a most important provision in order to maintain continuity of income for the doctor, who otherwise will suffer serious financial loss whether he participates or not.

(6) The right of any patient to be treated privately by their own or any other doctor if they so desire it, with adequate safeguards.

(7) The right of a doctor to appeal to an independent tribunal in case of dismissal from the Service.

There may be other very necessary conditions of service which may occur to others, but those enumerated above appear essential conditions to me.—I am, etc.,

Atherston, Manchester.

K. V. DEARIN.

Concessions

SIR.—We, three interested general practitioners, have followed the present Health Service controversy as far as we are able both in the medical and lay press. We are puzzled by one point. The Minister claims persistently and emphatically to have made concessions to the profession. We can only list two: (1) the granting of private beds in hospitals to the consultants; (2) the setting up of a legal commission on partnerships. Of these two moves the first is suspect as an attempt to split the ranks of the profession; the second was only made after all negotiation had broken down. This can hardly rank as an effort of conciliation, but rather as a propaganda point for Parliament and the public.

Are we wrong in believing that all the alterations suggested by the B.M.A. have been granted by the Ulster Parliament and incorporated in an otherwise identical health service in that country? If this be correct surely it is a point that could be made widely public. It would show that at least one body of responsible people consider our suggestions reasonable.—We are, etc.,

IDA M. WILL.
J. H. FRANCIS.
R. A. FURNESS.

Nottingham.

* Right of appeal to the Supreme Court, absence of powers of direction, and remuneration by capitation fee only are all incorporated in the Northern Ireland Act. The Bill was discussed in a leading article in our issue of Sept. 20, 1947 (p. 459).—ED., B.M.J.

Retain Goodwill

SIR.—Notwithstanding the plebiscite results, I view the present situation with grave apprehension. The most disquieting aspect is the negative attitude of the Conservative Press and Party. They both seem to have overlooked the fundamental differences between ourselves and Mr. Bevan and to consider that a little give and take on both sides will settle the matter. My own gravest fear has been that the Minister would say to us: "You are now asking for three major concessions: I am prepared to grant you two if you will meet me on the third. You shall have no basic salary, you shall have an appeal to the courts, and I shall buy your practices." To my horror a letter in *The Times* from our respected leader Lord Horder appeared to me to lead up to the same solution. Lord Horder laid far too much stress on the appeal to the courts and basic salary and scarcely any on the purchase and sale of practices. Possibly as a consultant he does not fully realize what ownership of our practices means to us G.P.s.

Obviously somebody will have to give way on some points before July 5, and my own opinion is that we should be wise as a profession to concentrate on the one issue of retention of the goodwill of our practices. If we give way on this one point we shall have lost the battle and opened the gates for totalitarianism and even eventual Communism. I regard the issue as a battle between Hippocrates and Marx.

The B.M.A. has done wonderfully well in conducting this campaign, but the real battle is only just beginning. Against us we have all the forces of the Left deployed with cunning and craft, which may well divide our ranks unless we can stand firmly together. From careful observations I personally suspect that there are quite a few chicken-hearted doctors who must "rat" on us, not because they like the Act but because they fear financial sanctions from Whitehall. If we accept the absence of appeal to the courts and the basic salary we may not get our ideal, but we shall still be owners of our own practices, "master of our soul and captain of our fate." As somebody has got to compromise, let us instruct our B.M.A. representatives to fight to the bitter end to retain our own practices but to be prepared to give way on the other two points.

We can expect no help from the Conservative Party on this issue. They are themselves tainted with the virus of bureaucratic control, and if we fail to agree on this one issue we shall, as I personally view the situation, have lost the fight and signed ourselves up for serfdom, a fate which we shall richly deserve as an educated and liberal profession, because we have not the excuse of ignorance. A study of European (particularly German) history during the last decade shows clearly how a State medical service is the essential step towards securing full control of the workers; it also helps one to realize why Mr. Bevan is so keen to get our practices.

To summarize: the State Service is coming anyhow; if we can retain our ownership of our practices we can retain our independence and try and make the best of it. If we give in on this one point we are sunk and lost for ever; no regrets afterwards will be of any avail. Let us not then bother too much about public and political opinion. We as a profession have expressed our honest sincere opinion of the Act, and we are the only people on this earth who know how to run a successful medical service for Great Britain—it happens to be our own special job. We shall never unite on all three basic principles; let us throw overboard the two that don't matter vitally and stick to the third one, which means professional life or death.—I am, etc.,

Holcombe Regis, Somerset.

JOHN V. MANTON.

The French System

SIR.—It is with some trepidation that I enter the arena of the N.H.S. controversy. It is unfortunate, if inevitable, that the translation of our principles into practical issues should revolve around ways and means of remuneration. I feel the solution does not rest with capitation fee (with or without basic salary) but with remuneration per item of service. I believe we could with advantage study the system which works satisfactorily in France to-day. As far as the general practitioner is concerned this is in outline how the system works.

Agreements are made between the regional medical unions and the regional social security headquarters concerning minimum fees for various items of service—consultation at surgery, domiciliary

visit (day, night, Sundays), and minor operations. The patient pays his doctor, who initials a receipt provided by the social security organization. The fee is later refunded minus 20%.

The advantages of this system are many and amply compensate the slightly more complicated administrative machine which is needed. (a) The patient has complete freedom to choose or change his doctor. (b) The doctor-patient relationship is preserved, as the State enters into a contract with the patient and not with the doctor. (c) The doctor is not called out for trivial complaints, as the patient must pay out of his own pocket one-fifth of the fee. (d) The more experienced doctor or the older physician may raise his fees (within accepted limits) to lessen the burden of his practice.

This system works well, and I have no doubt a similar system could be devised to meet our needs.—I am, etc.,

London, N.W.1

J. DELAFRESNAYE.

Implement the Plebiscite

SIR.—At a local general meeting of the profession convened on March 7 to consider the resolutions proposed by the B.M.A. Council at the next Special Representative Meeting I proposed the following resolution, supported by one of my seniors:

That after consideration of the plebiscite result the Representative Body recommends the profession not to take any action to implement the Health Acts of 1946 and 1947 until they have been amended to meet the demands of the profession.

While it was received sympathetically, it was rejected. The last resolution of the Council was passed by a large majority, a minority not voting.

I would like to know how the Council and the supporters of their first resolution defend it in the light of what we have learnt about the Health Acts. We know that they are a political measure, the main purpose of which is to centralize the control of certification in the hands of the Government, that they are the last link in a chain being forged, not by any one political party, which will have as its effect the delimitation of individual freedom. We know that the Government is determined to carry out its policy. We know that our previous effort to elect the Government has given us nothing, not even the sympathy of the public. We know that we have an overwhelming majority in the profession who disapprove of the Act. I would suggest that a mandate placed in the hands of the B.M.A. Council is the logical consequence of such a position.

Further, that such a resolution as mine is derived from a realistic tendency may well be a description of psycho-analytical fact and in that it is mere description—it is not to the point. The B.M.A. is a democratic institution, where it is for the members to make clear to the Council what is to be the policy of that Association. The first resolution of the Council is not a statement of policy but merely a hope and an opinion. At this meeting the Council were not given any line of policy to enact the results of the plebiscite.

Especially as there are at least a minority who share these views I venture to record them, and would like the Council and its supporters to take this matter up and explain the idea behind the first resolution. Failure to implement the plebiscite will result in the disintegration of our majority if the profession does not with decision to maintain one of the last bastions of freedom.—I am, etc.,

GEORGE H. BLAIR.

Benefits for Doctors' Wives

SIR.—I have read with interest and some sympathy of the formation of a League of Doctors' Wives. I feel, however, that the League's public activities in the national press the League has itself open to charges of misrepresentation of the position of the doctors' wives, and so I wish to express a few doubts of light in the form of State aid to the doctors' wives enjoyed up till now and which we have lost since the appointed day.

The doctors' wives have been in the mind of military age was the only way in which the reasonable provision for the doctors' wives could be made, joining a League of Doctors' Wives. The League's public activities in the national press the League has itself open to charges of misrepresentation of the position of the doctors' wives, and so I wish to express a few doubts of light in the form of State aid to the doctors' wives enjoyed up till now and which we have lost since the appointed day.

GEORGE H. BLAIR.

Symmetrical Gangrene in the African

SIR.—We have read with great interest Dr. M. Gelfand's excellent article on symmetrical gangrene in the African (June 14, 1947, p. 847). The possibility arises that the disease may have a similar aetiology to the epidemic thrombophlebitis described by us¹ in the East African Command during the War. The following are points of resemblance:

1. Dr. Gelfand's six patients were seen during the same period as our cases in Kenya and Somaliland.
2. The age and sex incidence was similar (he only saw the disease in males, usually between the ages of 20 and 35).
3. Oedema preceded the gangrene in all his cases. Many of our patients suffered from oedema without evident thrombophlebitis although the pathology of these and of the cases of obvious phlebitis was undoubtedly identical.
4. Two of our patients developed gangrene of the lower limb, arterial thrombosis being found at operation. Both cases presented as thrombophlebitis with oedema, which was later complicated by arteritis.
5. Most of our cases were preceded by venepuncture. One of Dr. Gelfand's patients had received injections of quinine for cerebral malaria, but the route of administration is not stated. The Wassermann reaction was positive in two of his cases. It is possible that these patients may have received anti-syphilitic treatment at some previous date.

The symmetrical character of Dr. Gelfand's cases is not incompatible with our theory, for 29% of our cases of thrombophlebitis involved both lower limbs. Had arteritis been a more frequent complication it is likely that gangrene would have been bilateral in a similar ratio. Is it not possible that mild thrombophlebitis was more widespread in Southern Rhodesia than appeared from hospital admission? An African in civilian life would probably fail to report for treatment of a mild, perhaps transient, attack of oedema of the leg. It would be surprising if a disease which was attacking so many East African troops in Kenya and Somaliland did not affect a proportion of Africans in civilian life. Fisher and Lendrum² describe tropical primary phlebitis in the neighbouring territory of Northern Rhodesia.—We are, etc.,

A. D. CHARTERS.

Exo-erythrocytic Forms of Malaria Parasite

SIR.—In the paper on the "Pre-erythrocytic Stage of Mammalian Malaria" by Drs. H. E. Shortt, P. C. C. Garnham, and B. Malamos (Jan. 31, p. 192) it is stated that the curtain on the gap in the cycle of events was lifted in the case of avian malaria by James and Tate in 1937, when they described the exo-erythrocytic cycle in *Plasmodium gallinaceum*. Such description had been preceded by the discovery of Raffaele of the unimpregnated stages in canaries of *Plasmodium relictum*.

In the first paper of S. P. James and P. Tate (*Parasitology*, 1938, 30, 128) it is stated that "Raffaele was the first to recognize that in *P. elongatum* there is a definite schizogonic cycle of development in cells of the reticulo-endothelial system in addition to the cycle in erythrocytes. Raffaele also demonstrated (*Riv. Malariol.*, 1936, 15, 318) that schizogony takes place in leucocytes or endothelial cells after heavy inoculation of canaries with sporozoites of *P. relictum*. . . . Unpublished work of one of us has confirmed Raffaele's results, that endothelial schizogony of *P. relictum* occurs in canaries which have been inoculated with sporozoites." Raffaele has also shown that the exo-erythrocytic forms appear only towards the 6th and 7th day after the inoculation of sporozoites. So the priority of Raffaele's discovery in avian malaria cannot be questioned, and no less incorrect is the statement in the annotation at p. 204 of the same issue of the *Journal* in which none of the names of the researchers in this field have been omitted with the exception of Raffaele's name.

The statement in the annotation that "evidence of a convincing nature is at last brought forward that the cycle of development of the malarial parasites in mammals is exactly analogous to that occurring in birds" comes many years late, as Raffaele had already described (1937-40) bodies belonging to the exo-erythrocytic cycle in man. The authors of the paper dismiss too easily the importance

of Raffaele's findings by saying that they have not been confirmed or received any support. But it is just that negative assumption that needs support, a support that would exact a long painstaking work as was Raffaele's work.

I am sure that your readers may be surprised in learning from Davey that to succeed in finding these forms, with the same difficulties that one meets in finding them in a six-days-old chick, it would be necessary to inoculate in the human the contents of 50,000 infected salivary glands. All malariologists who took the trouble of looking at Raffaele's smears have not hesitated in considering them as belonging to the exo-erythrocytic stage. I think that the authors' findings in the monkey is a confirmation of Raffaele's work on man. By the way, owing to the authority of Raffaele in that field his observations should have been accepted.

Before finishing this letter I feel the need of reminding your readers of the high intellectual merit of James in the discovery of the exo-erythrocytic stage. Considering all the proofs against Schaudinn's theory he postulated the necessity of a new stage between the sporozoite and the infection of the red blood cells. This working hypothesis was published in its completeness by Ruge (*Deutsch. med. Wschr.*, 1936, 62, 1869) and has been proved true by successive work. I am glad to give homage to the memory of James as the malariologist to whom the experimental malaria owes the most interesting clinical results.—I am, etc.,

Istituto di Malariologia Ettore Marchesiana,
Rome.

G. BASTIANELLI.

Swine Erysipelas Infection in Man

SIR.—I am interested in the concluding statement made by the president of the Section of Comparative Medicine of the Royal Society of Medicine (Feb. 28, p. 404) in which he asked whether the susceptibility of man to swine erysipelas might not be much higher than was commonly thought. Personally, I have found it comparatively common—its incidence twice as frequent as erysipelas in my practice. I meet at least two cases of the cutaneous type and sometimes as many as five of these cases in a year. I must have seen about fifty cases or more during the past eighteen years.

It is variously known as erysipeloid, crab cellulitis, or reticular lymphangitis. There is almost always a history of a scratch or minor cut from a meat bone or a skinning or butcher's knife. The infection has occurred in my cases among butchers, gamekeepers, cooks, farmers, who have been skinning dead sheep found on the hill, and not infrequently in housewives. A few have occurred from fish-bone scratches.

The condition has a seasonal incidence from August to February. It usually occurs on the finger, commencing as a purple patch, which extends over the finger, clearing in the centre and working towards the tip and the palm. There it commonly proceeds to travel down a neighbouring finger to its tip. It has a slowly spreading, sharply defined, purple, raised narrow margin. It is itchy and hot, but never really painful. On one occasion only have I seen a mild lymphangitis to the middle of the forearm. It resolved spontaneously with splinting of the parts. Suppuration never occurs. The erysipeloid undergoes spontaneous cure in about three weeks in most cases.

Until two years ago I treated these cases with 10% ichthyol ointment applied every two days on lint, knowing that it would at least do no harm. I have never seen a case relapse with this treatment although relapse is said to be common. I do not claim that the ichthyol had any particular effect on the infection, but some method of treatment had to be given to satisfy the patient. Lately I treated two cases with 200,000 units of penicillin night and morning, but abandoned it in both cases after five days as no improvement occurred. This autumn I was fortunate in having an elderly housewife with the condition, whose daughter, a nurse, administered 50,000 units of penicillin three-hourly for seven days. This case was less than a week old and too early to undergo spontaneous cure. After four days of penicillin treatment the lesion had completely disappeared, and no recurrence took place. It is obvious that ordinary massive dosage night and morning is insufficient, but 400,000 units daily by three-hourly injections effects cure in some cases. Higher dosage might of course be necessary in others.

I feel sure that swine erysipelas occurs much more frequently in man in rural areas than is commonly supposed.—I am, etc.,

Brideend, Isle of Islay, Argyll.

CAMPBELL M. MCINTYRE.

Rarer Manifestations of Herpes Zoster

SIR.—The very interesting article on this subject by Dr. T. Parkinson (Jan. 3, p. 8) is bound to recall other unusual cases of herpes zoster. I remember to have seen a sequence of cases a few years ago which struck me already at the time as extraordinary but gained even more significance after reading his article.

The first case was that of an elderly man, patient A, who was admitted to hospital with herpes zoster of typical thoracic distribution. A few days later patient B was admitted for an amputation of his toes. While recovering from it he used to visit patient A in his room. About three weeks after his admission he developed a left facial palsy which took about one year before it had disappeared entirely. Patient A was admitted again several months later for post-herpetic pain and mental depression. At that time patient C, who was being treated for a diaphragmatic hernia with ulceration, visited him on several occasions. After about a fortnight he developed a herpes zoster of typical abdominal distribution. Somewhat about the same time patient D was recovering from a lumbar rhizotomy. He too visited patient A now and then. Soon after his discharge he consulted me for a paralysis of the left thoracic nerve which had affected the serratus anterior muscle and the posterior portion of the deltoid.

These four cases are interesting inasmuch as two of them apparently were examples of "zoster sine herpete." They further seem to point to a carrier state in herpes zoster which possibly was present in patient A.

The relationship between herpes zoster and varicella is exemplified lately to me when I saw a man suffering from herpes zoster and his wife getting an attack of varicella about three weeks later.

Finally it is worth recording the case of a 6-year-old boy who had been under radium treatment for sarcoma after abdominal exploration and came to see me for a herpes zoster with a distribution corresponding with L5.—I am, etc.,

Garton, Australia.

E. OLTRANEL.

Treatment of Subacute Bacterial Endocarditis

SIR.—I agree with much that Dr. Florence M. E. Dainton (Feb. 14, p. 317) and Mr. B. Waters (Feb. 28, p. 416) have written on this subject. Nevertheless I do feel that the importance of infected teeth, apical granuloma, and possibly tonsils as potential sources of bacterial leakage leading to relapse has not been emphasized.

Therefore may I add that I have shown elsewhere (*Lancet*, 1947, 2, 807) that penicillin-sensitive organisms can thrive in a dead tooth pulp in a subject receiving massive doses of penicillin.—I am, etc.,

Liverpool.

JOHN HALLAM.

Breast-feeding in Erythroblastosis Foetalis

SIR.—The practice of weaning infants with haemolytic disease because the mother's milk contains antibodies has been based on circumstantial evidence and speculation on the possible harm that might result to the baby rather than on scientific proof. The question of breast-feeding erythroblastic babies is of such importance that an authoritative opinion based upon actual investigation should be welcome. Dr. I. A. B. Cathie's observations (Oct. 25, 1947, p. 650) that there is no experimental evidence to prove that Rh antibodies are demonstrably absorbed into the blood stream by way of the alimentary canal and the conclusion that weaning of such infants is not justified are therefore of great interest. It is also interesting to note that at the Hospital for Sick Children, Great Ormond Street, London, it has been the practice to breast-feed such children whenever this can be done, irrespective of the antibody content of the breast milk, and that their clinical progress has not suggested any relationship between the antibodies in the milk and the duration of the haemolytic process.

I wish to make the following comments on these observations. The finding that Rh antibodies are not readily destroyed by the gastric secretion of infants is significant, as it shows that they remain potent and may yet be absorbed from the alimentary canal. There is a fundamental difference between absorption through the placenta and from the alimentary canal. In the former, on entry into the foetal circulation the antibodies come into direct contact with the

come by introducing the element of infiltration; unfortunately for this view, in leather-bottle stomach with almost universal infiltration pain is at a minimum. The rigid fibrosis of carcinoma precludes the distension essential to the genesis of muscular visceral pain. Again the accompanying inflammatory cellulitis provides the explanation—recession or removal of the infective factor in stomach cancer by oral cleansing, gastric lavage, short circuit, etc., mitigates or relieves the pain entirely (incidentally also, as is too little known, the achylia). Hence the paradoxes that a man's best help in getting an early diagnosis of carcinoma of the stomach is to have a filthy mouth, and conversely, that in the edentulous carcinoma of the stomach is peculiarly latent. Pathology is one and indivisible, the most potent cause of fluctuations in symptoms throughout clinical medicine is the ebb and flow of inflammatory oedema.

But now Mr. Kinsella introduces the question of pain and haematemesis. Is this a Greek gift or a very subtle emphasis of the case I have outlined? Haemorrhage from "peptic" ulceration may be a slow trickle (the basis of the occult blood test) from the circumferential inflamed mucosa—gastroscopists will agree the origin is not granulation tissue in the ulcer floor—or brisk, or severe. Brisk, always recoverable, bleedings occur from erosions (the old "acute" ulcers), occurring indiscriminately as regards site. They are small, heal rapidly, and are never followed by chronic ulcer. They involve only the mucous and submucous coats, opening comparatively small vessels, and not holding them open and non-retractable by chronic fibrosis and oedema, and uncommonly involve the gastric musculature. In these erosions pain is but a transient, often absent, feature.

In chronic ulceration brisk haemorrhage may arise from erosions in concomitant gastritis (with clinical features as in the preceding instance), or from the opening of large extramural vessels by an exacerbation of devitalization and digestion. Rigidity of the surroundings prevents "natural" arrest of bleeding. Pain precedes and accompanies the bleeding, and its persistence indicates progression of necrosis and inflammatory reaction. Traditionally such cases have been treated by either complete prohibition of intake or merely sips of water—such a regime leads quickly to a total cessation of gastric function, motor or secretory. Hence the age-old fasting treatment gives as rapid a recession of ulcer symptoms as any of the most elaborate drug and diet treatments, particularly if stimulation of gastric peristalsis by iced water and the epigastric ice-bag is precluded. In fine, the treatment of haemorrhage is that best calculated to diminish ulcer symptoms: persistence of pain, as noted in the Goulstonian Lecture, is of bad prognosis, indicating despite such treatment an extension of the ulceration. That the clot in the floor of the ulcer prevents the deadly HCl from getting at and stinging the ulcer is most difficult to believe from any *a priori* chemical consideration; muscular atony from acute anaemia of haemorrhage is at least a credible accessory factor.

The haemorrhage-pain clinical features of ulceration offer therefore no contradiction but rather a substantiation of the cellulitis-myoegenous view of gastric pain in ulcer and carcinoma. My original letter was a challenge to the radiologists in their claim to demonstrate healing of "peptic" ulcers: with them must now be included the physicians in the indictment that they fail to correlate morbid anatomy with the signs and symptoms of gastric disease.—I am, etc.,

London, W.1.

C. JENNINGS MARSHALL.

Oral Intubation and the Davis Gag

SIR.—I must thank Dr. I. W. Magill (Feb. 28, p. 417) for his observation on the tongue plate for the Boyle-Davis gag, which I described in the *Journal* of Feb. 7 (p. 267)—needless to say I claim no originality for the device, the principles of which must have occurred to every E.N.T. surgeon. I cannot agree, however, that intubation is not advisable for tonsil operations, though it is far from essential. As he admits that it is suitable for the more difficult and lengthy operation of cleft palate, however, I cannot see why it is not, to say the least, preferable for even short cases. After all it is a simple matter to put in a tube, and the increased safety and control of anaesthesia (on both patient and surgeon) are surely adequate compensation for cutting the hourly production rate in children down to five or six dissections.

He puts emphasis on the ability of the surgeon and the anaesthetist. Is the anaesthetist justified in assuming that the surgeon is "capable," by which I presume he means the operation is relatively rapid and avascular? These are optimum conditions—I feel it is safer policy to prepare for the worst.—I am, etc.,

J. S. C. MONRO.

Darlington.

The Danger of Intubation under Trichlorethylene

SIR.—Dr. Gordon Ostlere has recently published two articles in the *Journal* concerning the use of trichlorethylene (April 5, 1947, p. 448, and Jan. 31, p. 195). The first dealt chiefly with the use of curare in "poor-risk patients." It certainly confirmed my own belief and experience in the wide range and usefulness of trichlorethylene especially when used in combination with curare for such cases. In the second article the toxic effects as shown by cardiac arrhythmias are mentioned and Dr. Ostlere points out that trichlorethylene should not be used in the presence of an existing cardiac irregularity, and that it should be replaced by ether where an irregularity occurs and persists with trichlorethylene.

Several fatalities have occurred when this drug has been used, but one cannot always blame the drug directly—in fact it is probably safer to lay the blame in most cases partly to the technique used and/or partly to some concealed or unappreciated condition of the patient which may even have been undetectable. I am unable to present any technical details regarding recorded fatalities with this drug, but I would like to mention two cases in my own experience.

Case 1.—A man aged 49—poor colour and rather tired—was suffering from right renal calculus. B.P. 160/100. Blood urea normal. Left kidney normal. Heart and lungs, n.o.d. It was proposed to perform a right nephrectomy. "Omopon" (pr. 113 (22 mg.), and scopolamine, gr. 1/150 (0.43 mg.), were given and he arrived in the theatre more than usually drowsy. 0.4 g. thiopentone was then administered followed by gas-oxygen and trichlorethylene. Respiration soon answered to carbon dioxide stimulation and brief intubation performed at the first attempt. There was immediate reflex spasm and breath-holding, the breath being held at the expiration of a pronounced cough. In an attempt to relieve the spasm I administered curare 15 mg. and oxygen under pressure. I hoped that the incision might prove a stimulus to the respiratory centre, but almost immediately after the incision had been made the heart ceased to beat. Remedial measures were instituted and the heart eventually restarted by massage by an incision through the diaphragm. Voluntary respiration returned very slowly and then more rapidly, changing later to Cheyne-Stokes respiration. He was then removed to the ward and transferred to an "iron lung," being taken out at intervals. Always there was a return to Cheyne-Stokes respiration. He died thirty-six hours after the incident without regaining consciousness. Post-mortem examination showed marked atheroma of aorta and a hypertensive thick-walled heart. The coronary arteries were pipework in character and so patented by atheroma that their lumina were invisible. The cerebral arteries of similar calibre. Death was therefore due to card. ac. failure as a result of the coronary atheroma and essential hypertension.

There is little doubt that this patient had not long been ill with it, but I feel he would have died more peacefully and in his home had a deeper plane of anaesthesia been used for the period of intubation.

Case 2.—A well-built young man, over 6 feet tall, was taken to a gland excised in his neck. Exactly the same induction technique was used. Breath-holding occurred following intubation, but the pulse remained full and regular. Here I felt it was justifiable to administer curare. I gave him 10 mg. curare, but the time from the patient in the anaesthetizing room. A gradual relaxation of spasm occurred and a return to normal respiration so that the operation was continued successfully under gas-oxygen and trichlorethylene.

These two cases I think emphasize sufficiently the danger of intubating some patients under too light an anaesthetic, and such cases should be brought out into the open.

Some anaesthetists advise using a cocaine spray before all cases requiring intubation. I would say this is unnecessary as a routine and only serves to upset a number of patients. Some prefer to intubate whenever possible through the mouth. Where relaxation is not required and the patient is well built and possesses a full upper and lower set of teeth the nasal route is often to be preferred. And finally a discussion in this journal has recently been taking place concerning the technique of Dr. Bourne, of intubating under almost maximum doses of thiopentone and curare.

We have therefore two extremes—very light and very deep. In view of possible dangers I consider it unsafe to make intubation under trichlorethylene a routine technique unless the larynx has been well co-anesthetized. Rather would I suggest that laryngoscopy should be performed and a tube introduced under cyclopropane or ether, and then possibly a change made to trichlorethylene as soon as the curare has been given or the patient has settled

HEPASTAB FORTE

BRAND

CONCENTRATED LIVER EXTRACT

HEPASTAB FORTE is a highly concentrated extract of liver which has been prepared in our Nottingham laboratories as the result of research conducted by our own chemists in co-operation with clinicians in this country and abroad. It contains all the known anti-anæmic factors of liver, is highly refined, painless on injection and highly concentrated. Each 1 c.c. of Hepastab Forte is obtained from 100 gm. of liver and is therapeutically equivalent to 4,000-5,000 gm. of fresh liver by the mouth.

Ampoules of 1 c.c.: single ampoules, boxes of 3, 6 and 12 ampoules. Rubber-capped vials of 10 c.c.

ANAHÆMIN B.D.H.

In Neurological Complications of Pernicious Anæmia

The hæmopoietic factor as presented in Anahæmin B.D.H. is essential for the prevention of subacute combined degeneration of the cord. Other substances, such as folic acid, will produce an adequate hæmatological response but allow neurological degeneration to appear and to progress unchecked. Potent liver preparations must be regarded as essential for the satisfactory treatment of pernicious anæmia.

Each batch of Anahæmin B.D.H. is clinically tested before issue.

THE BRITISH DRUG HOUSES LTD. LONDON N.1

ANAL. 2.113

in Staphylococcal Infection

An ointment of proved value in staphylococcal infection, particularly syphilis barbae, syphilis vulgaris, and tinea sycosis, possessing noteworthy qualities for promoting tissue repair. Impetigo contagiosa is among other dermatological conditions which have responded favourably to "Quinolol" therapy. In 1 oz. and 15 oz. jars.

FORMULA

"Quinolol" (Chlorohydroxy quinolol) 0.5 gm., Benzoyl Peroxide 10.0 gm., Aromatic Oil 0.25 gm., White Petrolatum, Lanolin Anhyd. decd. as q.s. 100 gm.

GLYCODEINE

GLYCODEINE IS A VALUABLE SEDATIVE FOR THE RELIEF OF IRRITABLE COUGH, ESPECIALLY IN PHTHISIS, BRONCHITIS AND DYSPNOEA.

IT IS ALSO A USEFUL LINCTUS FOR THE TREATMENT OF ASTHMA AND LARYNGITIS.

GLYCODEINE IS EXEMPT FROM THE REGULATIONS OF THE DANGEROUS DRUGS ACT.

FORMULA: Codeine Phosp. 0.4, Liq. Tolu 13.5,
Syr. Prunl Serot. 13.5, Glycerin ad 100
Each dram contains $\frac{1}{2}$ grain Codeine Phosphate.

It is supplied for dispensing
in bottles of $\frac{1}{2}$ lb. and
1 lb. in bulk.

committees under the Act, retaining our present position with regard to Local Executive Committees. I consider this to be of paramount importance, as it would prevent the election of some of the Minister's stooges. A compromise on the above lines would possibly enable us to enter the Service happily.

The Issue is Freedom

Dr. H. A. FAWCETT (Guildford, Surrey) writes: The issue now is no more nor less than freedom (reasonable and proper) versus power dictatorship (with a clear political and partisan bias), whether vested in one person or a small clique, in the name of a meaningless, abstract ideology called the "State." And although, at the moment, it appears chiefly to affect doctors, it is already (and will be increasingly) the vital concern of everyone, not only in these once blessed isles but all over the world. I do not think that this tremendous issue, now in its first (and maybe its last) great test here, is sufficiently or widely enough realized even in our own profession, and certainly not by the public in general; nor the fact that we as a body are given the privilege and opportunity of leading this first "crusade" against this insidious and growing evil. Moreover, we have a strength and justification (without in any way neglecting our professional duties or causing that suffering and loss inseparable from ordinary industrial disputes and strikes) almost unique, which, if properly exercised in unity, must not only win its narrower and more domestic battle but kindle a torch of hope and encouragement to all who still value legitimate freedom and elementary individual rights. Moreover, once lost, this splendid chance may never come again—not anyway in peace and in order. . . .

Disciplined Use of Liberty

Dr. K. W. TOOP (Croydon, Surrey) writes: We have now to tell the nation what we stand for. We want freedom, but we must convince our fellow countrymen that we mean to make right use of it. We want freedom to improve our health work, freedom to distribute ourselves with regard not to wealth but to usefulness. Can we not publish a plan for that disciplined use of liberty which has always been the backbone of the profession and of democracy?

Appeal to the Nation

Dr. E. H. STRANGE (Rushden, Herts) writes: Our best line for presenting our case is to appeal to the nation, showing that we are marked out for State control . . . because we are necessary agents in the complete State enslavement of the working classes. "Direction of labour" would be ineffective if the loop-hole of physical incapacity is not guarded by controlled State agents. It is useless to rely upon the political opponents of the present Government. The Conservative Party and the Conservative Press are deeply imbued with the modern notion of power politics, the omnipotent and omniscient State, and they do not understand wherein an honourable profession differs from a corps of salaried technicians.

Unpaid Civil Servants

A DOCTOR'S WIFE writes: It strikes me that the main practical factor which will decide whether or not Mr. Bevan's health plan will work is the general practitioner's wife. Should she be unwilling to accept the status of unpaid Civil Servant, neither Mr. Bevan nor his numerous but possibly uninformed supporters in the House of Commons will be able to make their own plan work by July 5 of this year. . . . Fortunately the time has not yet arrived in England when politicians can interfere in the private lives of the individual to the extent of coercing some housewives to use their own homes as surgeries of the State. . . .

Held Together

Dr. R. E. ARANGO (London, W.2) writes: With regard to the doctors and the National Health Service Act, 1946 . . . what they strongly feel is that with the Act as it stands they are being denied their right to work if they choose to stay out.

The Act indubitably states that doctors have the choice of staying out and remaining in private practice, but that is a hollow and valueless concession, worth no more than the ink it is written in; for in reality although the Act ostensibly does not deny them directly the right to work, yet indirectly it forcibly entices the patients away from them towards the "free" Health Service. . . . And then if those who stay out want to sell the goodwill of what remains of their practice, there will be nobody to buy, for the younger doctors will have tended to choose the line of least resistance and entered the Health Service to become eventually State medical slaves. If doctors do not hold together and let the Act be stillborn until a good one be conceived, the price to pay by those who still love and choose freedom and dignity will be but ruin and starvation in their loved profession. . . .

Treatment of Prickly Heat

Dr. A. C. BRYSON (St. Mawes, Cornwall) writes: The interesting correspondence on this subject prompts me to give my experience. Some thirty years ago Dr. Harston, of Hong Kong, published a

book on the treatment of subtropical diseases of children. In this he advocated the use of perchloride of mercury for this complaint—the prescription being aq. colognensis 3ii made up to 7i with lotio hydrarg. perchlor. 1:2,000. This was put up in a sprunk-top bottle with directions to dab freely affected parts and allow to dry. I regret that I cannot give the date of publication as my library was confiscated by the Japanese when I was interned on Dec. 8, 1941.

In the very distressing cases complicated by secondary infection with pyogenic organisms in the scalp and frontal region, untreated by the band of the topee, treatment twice daily with a thick layer of mercurial soap, such as "Afridol," and left to dry for five minutes has seldom failed to give complete relief in two days.

Oxygen Cylinders

Dr. REX BINNING (Hove, Sussex) writes: I am prompted by a recent experience to draw attention to the dangerous and widespread practice of covering the oxygen cylinders used in hospitals and nursing homes with a bag, which is tied round the shoulders of the cylinder and so completely obscures the distinguishing marks painted thereon.

I asked for a cylinder of oxygen and was given a cylinder containing oxygen 93% and carbon dioxide 7%. Fortunately I had taken the precaution of pulling the cover down from the shoulders of the cylinder and thus observed the white and green band, and no harm was done. The British Oxygen Company and Mr. Charles King have gone to considerable trouble by the institution of non-interchangeable couplings to prevent the wrong cylinder being used on anaesthetic machines. It is a pity that their efforts should be completely nullified by theatre owners and others continuing a practice for which there can be no justification.

Herpes Zoster and Chicken-pox

Dr. HOWEL LEWIS (Swansea) writes: The letter by Dr. C. C. H. Chavasse on the above subject (Feb. 14, p. 315) reminds me of two cases in the converse order that I saw recently. A woman brought her young daughter to my surgery one evening with obvious chicken-pox. A week later the mother again saw me. She had developed a moderate attack of intercostal herpes zoster from which she has not yet recovered. It would be interesting to know if this sequence occurs very often. Roxburgh states that it is ten times less common.

Incidentally, how would one allay a severe post-herpetic neuralgia of the cervico-occipital type in an old man of 72? The popular anodynes have been used; a course of pituitary extract (B.P.) was given during the acute stage, and the usual analgesics in various combinations have been used to no effect, not to mention electrotherapy at the local hospital.

Natives of the Tropics

Dr. R. E. ARANGO (London, W.2) writes: Dr. L. Everard Napier states (Feb. 14, p. 317) that during his 26 years in India he referred to the natives of India as the "indigenous inhabitants," but why he did not call them by the simpler terms of "the people" or "the inhabitants" beats me. The only explanation I can conceive is that the foreign rulers of India considered themselves to be the people or the inhabitants that really mattered, and as they (the foreign Britishers) could not very well call the immense multitude around them "foreigners," so they in disdain called them "natives." It is to such a terminology that the people of India have been justly averse and sensitively prejudiced. . . .

* This correspondence is now closed—Ed., B.M.J.

Injection of Diabetic's Skin

Dr. T. S. L. JONES (Whitehaven, Cumberland) writes: The routine preparation of the skin for a hypodermic injection is by swabbing the area with spirit in one form or another. Now a normal person's skin is soft and pliable and offers slight resistance to a hypodermic needle—no more resistance than one would encounter by plunging the needle into a pat of butter. Consequently a hypodermic injection should be almost painless.

The skin of the diabetic, thanks to its daily anointing with spirit, is not a normal skin. It is almost as tough as leather and consequently a hypodermic injection into the tough skin of the diabetic can be a very painful process, broken needles being not uncommon, and periodically the patient has to seek a new area of skin which has not been toughened.

My plea is for the abolition of the tyranny of surgical spirit, and in substitution I would suggest ordinary cleanliness as achieved by the use of soap and water. I instruct my own diabetic patients to bathe the part with soapy water and dry with a towel, instead of swabbing with spirit, and they have all been grateful for my suggestion. Over a period of many months I have not encountered one instance of an injection site becoming infected, perhaps because the skin is in a healthy condition and not dehydrated.

In my own general practice I have not used spirit for a long time when giving a hypodermic injection.

Obituary

R. V. SOLLY, M.D., M.R.C.P., F.R.C.S.

Dr. Reginald Vaughan Solly died in Exeter on Feb. 19 at the age of 83. His father was Edward Harrison Solly, of Congleton, Cheshire. He was educated at Winchester and St. Thomas's Hospital, qualifying in 1887. After experience as a house-surgeon and as clinical assistant to the Skin Department of St. Thomas's Hospital he became house-surgeon at Bristol General Hospital. He graduated M.B., B.S. in 1888 and proceeded M.D. five years later. He took the F.R.C.S. in 1890 and the M.R.C.P. in 1910. He entered general practice in Exeter in the nineties, but had always been specially interested in pathology, and his enthusiasm led him to become the organizer of a separate pathological department at the Royal Devon and Exeter Hospital. In 1911 he was first to hold the new appointment of pathologist to that hospital. The accommodation allotted to him was inadequate, and subsequently a small laboratory was erected for his department and came to be known as "Solly's Temple." His appointment as pathologist involved also his appointment as assistant physician, a post which he held until 1923. He continued as head of the department of pathology until his retirement in 1931, when he became consulting pathologist and a life governor of the hospital. For some years he was also consulting medical officer to the Exeter Dispensary. He was one of the foundation members of the Association of Clinical Pathologists, which has just celebrated its coming of age. For many years he was secretary of the Devon and Exeter Medico-Chirurgical Society.

Dr. Solly was a keen entomologist with a special interest in Lepidoptera, both British and foreign. For over fifty years he was a member of the Field Club of the University College of the South West, which he served as president and lecturer. He had a fine collection of butterflies and frequently visited Southern France, particularly around Hyères, in search of rare specimens. He was an adept dry-fly fisherman, making his own flies, and he found time every week for a fishing expedition, often accompanied by one of his technicians. He spent many happy holidays fishing the Wiltshire rivers around Wylve and Mers. In 1902 he married Frances Anne Laura Buckingham, who predeceased him by a week. His publications included articles on rat bite fever, on Ludwig's angina, and on trichinosis.

L. A. R. writes: "Solly was highly cultured and widely read; of quick, nervous, sensitive, and highly diffident temperament; with a fine sense of humour, quick to an intense anger, which, however, always disappeared equally quickly like an April shower. He was a man of no commercial ambitions or interests, enjoying a wide popularity among his colleagues throughout Devonshire. No memoir of him would be complete without mention of the speeches annually demanded of him at the Exeter and South-West dinner. At this function his speech was always a main event, eagerly anticipated and delivered with a slightly hesitant characteristic of the man, but erudite and containing an element of spontaneity and dry humour."

Dr. James M. Solly, M.P., died suddenly at his home in London on Feb. 9 at the age of 56. He was educated at Queen's College, Belfast, and at Queen's University, where he graduated B.A. in 1911. He subsequently obtained the D.P.H., and the M.D. Later he took the M.R.C.P. For the last twenty years he was a physician on the staff of the Royal Free Hospital, London. Some years ago he was transferred to the staff of the Belfast City Hospital, where he had been clinical lecturer and had also been a member of the Belfast Medical Society. In the General Medical Council he was one of the top of the poll as one of the best of his generation. He was a very full and active member of the British Medical Association. Despite his many achievements he was a man with

less energy he found time to contribute articles occasionally to medical and scientific journals. His opinion was much sought after by his medical colleagues and his advice greatly respected. He enjoyed to the full the confidence of the medical fraternity in Northern Ireland and over the border. In Parliament he was a popular figure, and in the advocacy of his views, often directly conflicting with those of the majority—for example, on the question of the appropriation of hospitals by the Government—he offended no one. He stood for principle and never indulged in personalities. He was a man of the highest moral character and great generosity, lovable both for his sterling qualities and for his cheery optimism. In his own family circle he was seen at his best. To each member of his devoted family his loss is irreparable. He leaves a wife, four sons, and two daughters. To them we offer our sympathy.—E. M. H.

Dr. GEORGE WILSON died at his home in Nairn on Feb. 9 at the age of 80. Dr. Wilson was a native of Strichen, and was educated at Chanonry School, Old Aberdeen, and Aberdeen University. He took his M.A. in 1888, and graduated M.B., C.M. in 1891. He was the senior practitioner in Nairn, where he had settled in 1898. He was in the old Nairn Artillery Volunteers, and later became medical officer to the Inverness battery of the R.H.A., serving in the Middle East in the 1914-18 war. Dr. Wilson took a great interest in local affairs and was medical superintendent of Nairn Hospital and a trustee of Nairn Savings Bank. He had also been visiting surgeon to the Chalmers' Hospital and assistant visiting physician at the Banff District Asylum. In the early years of his practice he did his rounds on horseback and later owned the first motor-cycle in the district. He had been a member of the British Medical Association for over fifty years, and was chairman of the Banff, Elgin, and Nairn Division in 1922-3, and president of the Northern Counties of Scotland Branch in 1929-30. He is survived by his wife and four daughters.

Dr. JOHN WILFRED NUNN, of Hadley Green, Barnet, died suddenly on Feb. 11 at the age of 72. Dr. Nunn, who was born in Penzance, was a student at St. Bartholomew's Hospital, and qualified in 1900. He held hospital appointments at Stamford and at Guildford before settling in Hadley in partnership with the late Dr. Walter Mercer. His elder son, Dr. J. A. Nunn, entered the practice in 1933 and has since continued in partnership with his father. Dr. Nunn was on the staff of the Victoria Cottage Hospital and was medical officer to the Post Office and to the Queenswood School, Hatfield. In his younger days Dr. Nunn was a keen cricketer and lawn tennis player, and he and his wife had been active for many years in the Barnet Arts Club and other local organizations.

Medico-Legal

DEATH OF A DOCTOR

At the Assizes in Leeds on Feb. 25 Mr. Justice Byrne awarded damages of £15,025 with costs to the widow of a doctor. The defendants, the owner and the driver of a motor lorry with which the doctor collided when riding his auto-cycle last April, admitted liability. In the collision the doctor, who was 33, received fatal injuries.

According to a Press report¹ during the hearing of the case Mr. Justice Byrne was shown a document setting out the terms offered by the Minister of Health to general practitioners joining the new National Health Service. Counsel for the widow said that the doctor had bought a Darlington practice in 1945 for £3,000. In the first full year in which he worked there his income was £3,115, of which £763 came from private patients. The practice was growing steadily. Counsel said that if the doctor had joined the new health service the lowest gross income he would have received would have been £2,208. Counsel for the defendants said in view of what might happen to the profession the doctor might not have entered the service and would have had to depend solely on the income derived from private patients.

Mr. Justice Byrne said: "I am inclined to take the view that if he had remained outside the service the number of his private patients would have increased considerably."

¹ *Yorkshire Post*, Feb. 26, 1948.

Medical Notes in Parliament

The Minister and the Profession

Mr. DE LA BÈRE on March 4 asked the Prime Minister whether, in view of the necessity of obtaining the co-operation of a maximum number of the medical profession before July 5, 1948, he would consider appointing an independent arbitrator for the purpose of finding a solution to the present impasse. Mr. ATTLEE answered, "No, Sir." He said that matters which had already been decided by Parliament would not be a proper subject for arbitration.

Mr. DE LA BÈRE inquired whether the Prime Minister was fully aware of the grave position which must arise in July because he had refused to meet the views of the vast majority of the doctors. Did Mr. Attlee know that the people of the country wished to know why the Government had allowed this position to come to pass? Mr. ATTLEE said that did not give any justification for Mr. De la Bère's proposal. Mr. DE LA BÈRE said it gave every justification.

Air-Commodore HARVEY asked whether the Government intended to charge the public for a service if they were not in a position to supply it.

Hon. Members: Answer. No answer was returned, and Mr. WILSON HARRIS then asked would the Prime Minister be prepared to lend a hand himself in future negotiations if he should think that that would be likely to help matters? Mr. ATTLEE said he was prepared to consider any suggestion put before him.

Squadron-Leader FLEMING asked whether the House was to understand that no approach had been made up to date by either the B.M.A. or the Minister of Health upon this matter?

Mr. ATTLEE: To whom?

Squadron-Leader FLEMING: Each other.

Dental Opposition

Mr. BAIRD asked the Minister of Health what steps he was taking to prevent dentists who had publicly expressed their opposition to the National Health Service Act from serving on the local dental committees set up under the Act.

Mr. BEVAN replied on March 5 that he was taking no steps. He hoped that on a closer acquaintance with the National Health Service dentists generally would recognize its merits.

Honorary Staffs' Honorarium.—Mr. HASTINGS asked on March 4 whether Mr. Bevan knew that certain voluntary hospitals now receiving Treasury grants made the receipt of an honorarium by members of their honorary staffs dependent on resignation from their medical advisory committees; and if, in these cases, he would consider withdrawing the grant. Mr. BEVAN said Exchequer help was given before the appointed day to keep the hospitals going. The action mentioned would not in his view justify interference with the domestic affairs of these hospitals. Nevertheless, he deprecated such action.

St. Leonard's Hospital.—On March 4 Mr. HASTINGS asked the Minister of Health whether he intended to publish the report of the assessors appointed to investigate the training of nurses at St. Leonard's Hospital, Shoreditch; and whether a copy would in any case be supplied to the General Nursing Council and the London County Council for their guidance. Mr. BEVAN replied that it was not the normal practice to publish reports of persons appointed to hear appeals on behalf of the Minister of Health. He did not think there were grounds for making an exception in this case. If the bodies mentioned asked to be supplied with a copy of the report he would furnish one confidentially.

Colostomies and Clothing Coupons.—Mr. THOMAS BROOKS pointed out on March 4 that three clothing coupons had to be surrendered before a colostomy surgical belt was supplied. Mr. HAROLD WILSON replied that surgical belts of not more than 6 inches in width specially designed for a number of specified conditions, including colostomy, were available coupon-free, but coupons were required for other types which could not be thus clearly defined because some could be worn in place of other rationed undergarments. The Board of Trade was prepared to consider sympathetically applications for special allowances of coupons for wearers of colostomy appliances subject to the production of medical evidence.

Exchange Control Medical Advisory Committee.—Mr. GLENVIL HALL said on March 2 that as from March 1 no fees would be payable by applicants to receive foreign exchange for medical treatment abroad. In future all applications should be made through a doctor and not by the patient himself. The members of the Exchange Control Medical Advisory Committee were all distinguished medical specialists who since the foundation of the Committee had received no fees except £1,659 from applicants.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Feb. 27.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland. Figures of Births and Deaths, and of Deaths recorded under each of the 10 principal causes for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland. A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

1 Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

2 Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

3 The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

4 Includes puerperal fever for England and Wales and Eire.

Obituary

R. V. SOLLY, M.D., M.R.C.P., F.R.C.S.

Dr. Reginald Vaughan Solly died in Exeter on Feb. 19 at the age of 83. His father was Edward Harrison Solly, of Congleton, Cheshire. He was educated at Winchester and St. Thomas's Hospital, qualifying in 1887. After experience as a house-urgeon and as clinical assistant to the Skin Department of St. Thomas's Hospital he became house-surgeon at Bristol General Hospital. He graduated M.B., B.S. in 1888 and proceeded M.D. five years later. He took the F.R.C.S. in 1890 and the M.R.C.P. in 1910. He entered general practice in Exeter in the nineties, but had always been specially interested in pathology, and his enthusiasm led him to become the organizer of a separate pathological department at the Royal Devon and Exeter Hospital. In 1911 he was first to hold the new appointment of pathologist to that hospital. The accommodation allotted to him was inadequate, and subsequently a small laboratory was erected for his department and came to be known as "Solly's Temple." His appointment as pathologist involved also his appointment as assistant physician, a post which he held until 1923. He continued as head of the department of pathology until his retirement in 1931, when he became consulting pathologist and a life governor of the hospital. For some years he was also consulting medical officer to the Exeter Dispensary. He was one of the foundation members of the Association of Clinical Pathologists, which has just celebrated its coming of age. For many years he was secretary of the Devon and Exeter Medico-Chirurgical Society.

Dr. Solly was a keen entomologist with a special interest in epidoptera, both British and foreign. For over fifty years he was a member of the Field Club of the University College of the South-West, which he served as president and lecturer. He had a fine collection of butterflies and frequently visited Southern France, particularly around Hyères, in search of rare specimens. He was an adept dry-fly fisherman, making his own flies, and he found time every week for a fishing expedition, often accompanied by one of his technicians. He spent many happy holidays fishing the Wiltshire rivers around Wylve and Mere. In 1902 he married Frances Anne Laura Buckingham, who predeceased him by a week. His publications included articles on rat-bite fever, on Ludwig's angina, and on trichinosis.

F. A. R. writes: "Solly was highly cultured and widely read; of quick, nervous, sensitive, and highly diffident temperament; with a fine sense of humour; quick to an intense anger, which, however, always disappeared equally quickly like an April shower. He was a man of no commercial ambitions or instincts, enjoying a wide popularity among his colleagues throughout Devonshire. No memoir of him would be complete without mention of the speeches annually demanded of him at the Exeter and South-West dinner. At this function his speech was always a main event, eagerly anticipated and delivered with a visible shy hesitation characteristic of the man, but erudite and containing an element of spontaneity and dry humour."

Dr. FREDERICK MCSORLEY, M.P., died suddenly at his home in Belfast on Feb. 9 at the age of 56. He was educated at St. Malachy's College, Belfast, and at Queen's University, where he graduated in 1916. He subsequently obtained the D.P.H., and in 1922 proceeded M.D. Later he took the M.R.C.P.I. and was elected F.R.C.P.I. in 1930. For the last twenty years he had been honorary visiting physician on the staff of the Mater Infirmorum Hospital, Belfast. Some years ago he was also appointed visiting physician to the Belfast City Hospital. He was in daily attendance at both hospitals up to the time of his death. For many years he had been clinical lecturer and examiner for Queen's University, Belfast, and he had also examined for the Royal College of Physicians. In the General Election of 1945 he was returned at the top of the poll as one of the university members of Parliament. His was a very full life and he never spared himself either in the course of his medical or his political duties. He was a member of the British Medical Association and of the Ulster Medical Society. Despite manifold duties which would have overwhelmed a man with

less energy he found time to contribute articles occasionally to medical and scientific journals. His opinion was much sought after by his medical colleagues and his advice greatly respected. He enjoyed to the full the confidence of the medical fraternity in Northern Ireland and over the border. In Parliament he was a popular figure, and in the advocacy of his views, often directly conflicting with those of the majority—for example, on the question of the appropriation of hospitals by the Government—he offended no one. He stood for principle and never indulged in personalities. He was a man of the highest moral character and great generosity, lovable both for his sterling qualities and for his cheery optimism. In his own family circle he was seen at his best. To each member of his devoted family his loss is irreparable. He leaves a wife, four sons, and two daughters. To them we offer our sympathy.—E. M. H.

Dr. GEORGE WILSON died at his home in Nairn on Feb. 9 at the age of 80. Dr. Wilson was a native of Strichen, and was educated at Chanonry School, Old Aberdeen, and Aberdeen University. He took his M.A. in 1888, and graduated M.B., C.M. in 1891. He was the senior practitioner in Nairn, where he had settled in 1898. He was in the old Nairn Artillery Volunteers, and later became medical officer to the Inverness battery of the R.H.A., serving in the Middle East in the 1914-18 war. Dr. Wilson took a great interest in local affairs and was medical superintendent of Nairn Hospital and a trustee of Nairn Savings Bank. He had also been visiting surgeon to the Chalmers' Hospital and assistant visiting physician at the Banff District Asylum. In the early years of his practice he did his rounds on horseback and later owned the first motor-cycle in the district. He had been a member of the British Medical Association for over fifty years, and was chairman of the Banff, Elgin, and Nairn Division in 1922-3, and president of the Northern Counties of Scotland Branch in 1929-30. He is survived by his wife and four daughters.

Dr. JOHN WILFRED NUNN, of Hadley Green, Barnet, died suddenly on Feb. 11 at the age of 72. Dr. Nunn, who was born in Penzance, was a student at St. Bartholomew's Hospital, and qualified in 1900. He held hospital appointments at Stamford and at Guildford before settling in Hadley in partnership with the late Dr. Walter Mercer. His elder son, Dr. J. A. Nunn, entered the practice in 1933 and has since continued in partnership with his father. Dr. Nunn was on the staff of the Victoria Cottage Hospital and was medical officer to the Post Office and to the Queenswood School, Hatfield. In his younger days Dr. Nunn was a keen cricketer and lawn tennis player, and he and his wife had been active for many years in the Barnet Arts Club and other local organizations.

Medico-Legal

DEATH OF A DOCTOR

At the Assizes in Leeds on Feb. 25 Mr. Justice Byrne awarded damages of £15,025 with costs to the widow of a doctor. The defendants, the owner and the driver of a motor lorry with which the doctor collided when riding his auto-cycle last April, admitted liability. In the collision the doctor, who was 33, received fatal injuries.

According to a Press report¹ during the hearing of the case Mr. Justice Byrne was shown a document setting out the terms offered by the Minister of Health to general practitioners joining the new National Health Service. Counsel for the widow said that the doctor had bought a Darlington practice in 1945 for £3,000. In the first full year in which he worked there his income was £3,115, of which £763 came from private patients. The practice was growing steadily. Counsel said that if the doctor had joined the new health service the lowest gross income he would have received would have been £2,208. Counsel for the defendants said in view of what might happen to the profession the doctor might not have entered the service and would have had to depend solely on the income derived from private patients.

Mr. Justice Byrne said: "I am inclined to take the view that if he had remained outside the service the number of his private patients would have increased considerably."

¹ Yorkshire Post, Feb. 26, 1948.

Medical Notes in Parliament

The Minister and the Profession

MR. DE LA BÈRE on March 4 asked the Prime Minister whether, in view of the necessity of obtaining the co-operation of a maximum number of the medical profession before July 5, 1948, he would consider appointing an independent arbitrator for the purpose of finding a solution to the present impasse. MR. ATTLEE answered, "No, Sir." He said that matters which had already been decided by Parliament would not be a proper subject for arbitration.

MR. DE LA BÈRE inquired whether the Prime Minister was fully aware of the grave position which must arise in July because he had refused to meet the views of the vast majority of the doctors. Did Mr. Attlee know that the people of the country wished to know why the Government had allowed this position to come to pass? MR. ATTLEE said that did not give any justification for Mr. De la Bère's proposal. MR. DE LA BÈRE said it gave every justification.

Air-Commodore HARVEY asked whether the Government intended to charge the public for a service if they were not in a position to supply it.

Hon. Members: Answer. No answer was returned, and MR. WILSON HARRIS then asked would the Prime Minister be prepared to lend a hand himself in future negotiations if he should think that that would be likely to help matters? MR. ATTLEE said he was prepared to consider any suggestion put before him.

Squadron-Leader FLEMING asked whether the House was to understand that no approach had been made up to date by either the B.M.A. or the Minister of Health upon this matter?

MR. ATTLEE: To whom?

Squadron-Leader FLEMING: Each other.

Dental Opposition

MR. BAIRD asked the Minister of Health what steps he was taking to prevent dentists who had publicly expressed their opposition to the National Health Service Act from serving on the local dental committees set up under the Act.

MR. BEVAN replied on March 5 that he was taking no steps. He hoped that on a closer acquaintance with the National Health Service dentists generally would recognize its merits.

Honorary Staffs' Honorarium.—MR. HASTINGS asked on March 4 whether Mr. Bevan knew that certain voluntary hospitals now receiving Treasury grants made the receipt of an honorarium by members of their honorary staffs dependent on resignation from their medical advisory committees; and if, in these cases, he would consider withdrawing the grant. MR. BEVAN said Exchequer help was given before the appointed day to keep the hospitals going. The action mentioned would not in his view justify interference with the domestic affairs of these hospitals. Nevertheless, he deprecated such action.

St. Leonard's Hospital.—On March 4 MR. HASTINGS asked the Minister of Health whether he intended to publish the report of the assessors appointed to investigate the training of nurses at St. Leonard's Hospital, Shoreditch; and whether a copy would in any case be supplied to the General Nursing Council and the London County Council for their guidance. MR. BEVAN replied that it was not the normal practice to publish reports of persons appointed to hear appeals on behalf of the Minister of Health. He did not think there were grounds for making an exception in this case. If the bodies mentioned asked to be supplied with a copy of the report he would furnish one confidentially.

Colostomies and Clothing Coupons.—MR. THOMAS BROOKS pointed out on March 4 that three clothing coupons had to be surrendered before a colostomy surgical belt was supplied. MR. HAROLD WILSON replied that surgical belts of not more than 6 inches in width specially designed for a number of specified conditions, including colostomy, were available coupon-free, but coupons were required for other types which could not be thus clearly defined because some could be worn in place of other rationed undergarments. The Board of Trade was prepared to consider sympathetically applications for special allowances of coupons for wearers of colostomy appliances subject to the production of medical evidence.

Exchange Control Medical Advisory Committee.—MR. GLENVIL HALL said on March 2 that as from March 1 no fees would be payable by applicants to receive foreign exchange for medical treatment abroad. In future all applications should be made through a doctor and not by the patient himself. The members of the Exchange Control Medical Advisory Committee were all distinguished medical specialists who since the foundation of the Committee had received no fees except £1,659 from applicants.

INFECTIOUS DISEASES AND VITAL STATISTIC

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Feb. 21

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland. Figures of Births and Deaths, and of Deaths recorded under each of the four causes are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland. A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Measles and whooping-cough are not notifiable in Scotland, and the figures are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

¶ Includes puerperal fever for England and Wales and Eire.

EPIDEMIOLOGICAL NOTES

Vaccination and Inoculation

British subjects travelling abroad, particularly to the Tropics or sub-Tropics, may be exposed to the dangers of infectious diseases not normally prevalent in the United Kingdom. In a recent notice issued by the Ministry of Health, the Department of Health for Scotland, and the Ministry of Health and Local Government for Northern Ireland it has not been practicable to give for every country details of the diseases against which travellers from the United Kingdom should protect themselves in their own interest or against which a particular country requires persons entering it to be protected. Travellers are therefore advised to apply for details to the representative in the United Kingdom of the country to which they propose to travel. The following information may, however, serve as a general guide.

(a) All travellers abroad are advised to be effectively inoculated against typhoid and paratyphoid fever.

(b) The health authorities of certain countries—e.g., Australia—and some countries in the Tropics and sub-Tropics may require travellers to produce evidence of recent vaccination against smallpox—i.e., evidence that they have been vaccinated not more than three years and not less than fourteen days previously.

(c) Travellers to parts of the Far East where cholera is endemic are advised to be inoculated against this disease.

(d) Inoculation against typhus is advised for travellers to countries—e.g., in South-East Europe and North Africa—in which that disease exists.

(e) Travellers who have been in or who pass through those parts of Africa or South America where yellow fever is considered to be endemic are reminded that, when they enter other countries in which yellow fever does not actually exist but where the conditions favour its development—e.g., India—they may be detained at frontier quarantine stations if they do not possess a valid certificate of inoculation against yellow fever—i.e., a certificate issued not less than ten days and not more than four years previously. Special arrangements have been made for yellow fever inoculations to be given free of charge at centres in the United Kingdom.

When a traveller has been vaccinated against smallpox or inoculated against cholera, typhus, or yellow fever he should obtain, and carry with him, a certificate to that effect on the International Form. A certificate of inoculation against yellow fever will be issued on this form by the doctor carrying out the inoculation: for the other diseases the necessary form can be obtained by the traveller from the company with whom he has arranged his transport.

Discussion of Table

In England and Wales decreases occurred in the number of notifications of scarlet fever 97, acute pneumonia 83, diphtheria 31, whooping-cough 24, and cerebrospinal fever 18, while increases were recorded for measles 1,030 and dysentery 27.

The largest increases in the incidence of measles appeared in Lancashire 203, Warwickshire 147, London 117, Surrey 116, and Middlesex 102. The notifications of scarlet fever declined in most areas of the country; the largest fall was London 32, and the only exception to the general trend was a rise of 30 in Glamorganshire.

Small decreases in the incidence of acute pneumonia were recorded throughout the country; the largest fall was Durham 33. The largest of the local variations in the returns for diphtheria were decreases in Lancashire 11 and Durham 8. The local trends of whooping-cough fluctuated, and the largest change in trend was a decrease of 38 in London.

The chief centres of dysentery were Yorkshire West Riding 67 (Sheffield C.B. 25, York C.B. 25); Lancashire 40 (Blackpool C.B. 15); Middlesex 23; and London 19. The largest returns of acute poliomyelitis were 3 cases notified in London and in Yorkshire West Riding. Administrative areas with more than one case were Bristol C.B. 2 and Leeds C.B. 2.

In Scotland an increased incidence was recorded for measles 46, dysentery 17, and diphtheria 6. The rise in the notifications of dysentery occurred in the north-eastern area; 11 cases were notified in the city of Aberdeen and 10 in Banff County. The other large returns of dysentery were Edinburgh 14 and Glasgow 9. The notifications of diphtheria in Glasgow rose from 25 to 30; half of the total cases recorded in the country were notified in this city.

In Eire an increase was reported in the notifications of whooping-cough 36, primary pneumonia 15, and scarlet fever 12, while a decrease was recorded for measles 25 and diarrhoea and enteritis 9. The incidence of measles decreased through-

out the country. An outbreak of whooping-cough involving 14 persons was reported from Wicklow, Rathdrum R.D.

In Northern Ireland the total notifications of scarlet fever fell by 10. Whooping-cough reappeared in Belfast C.B. with 11 cases.

Week Ending February 28

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,710, whooping-cough 2,631, diphtheria 173, measles 7,312, acute pneumonia 732, cerebrospinal fever 31, acute poliomyelitis 24, dysentery 145, paratyphoid 3.

Medical News

Specialists to Visit Africa

The Secretary of State for the Colonies has appointed 18 specialists nine of whom will visit East Africa and nine West Africa. The Nuffield Foundation will finance the scheme for six years. The experiment originated from discussions between Prof. H. J. Seddon and the late Dr. W. H. Kaunitz. It is hoped that the visitors may be of help to colonial medical staffs, particularly those working in isolated posts.

Portuguese Medical Visitor

Prof. Augusto P. Celestino Da Costa, Professor of the Faculty of Medicine in the University of Lisbon, is spending a fortnight in Britain under the auspices of the British Council. He is Director of the Service of Clinical Analyses in the Lisbon State Hospitals, President of the Portuguese Anatomical Society, and Director of the Portuguese Institute of Histology and Embryology, which he founded. A visitor to Britain before the war, Prof. Da Costa is now renewing and making fresh contacts with colleagues working on research in histology and cytology.

Sir G. Gordon-Taylor in Greece

Sir Gordon Gordon-Taylor is visiting Greece for a three weeks' tour to lecture for the British Council on war surgery.

Medical Golfing Society

At a meeting of the Medical Golfing Society held recently under the presidency of Dr. A. Hope Gosse, Mr. A. C. Palmer was appointed Captain, and Dr. A. Lesley Lankester Honorary Treasurer.

Prize for Essay on Colonial Tuberculosis

A prize of 100 guineas will be awarded by the Council of the N.A.P.T. for an essay on "The Control of Tuberculosis in a British Colony." The competition is open to medical men and women in the British Colonial Medical Service who are of not more than ten years', or less than five years', medical standing. At least three years must have been spent overseas in a medical capacity. Competitors should describe their own proposals for a practical scheme for the clinical, social, and administrative control of tuberculosis, either in the British Colonies as a whole or in one or more of them separately. Writers should give their own opinions based on personal experience of public-health and anti-tuberculosis work. Essays should be sent to Dr. Harley Williams, National Association for the Prevention of Tuberculosis, Tavistock House North, Tavistock Square, London, W.C.1, to arrive not later than March 1, 1949.

Health and Air Travel

Under the Public Health (Aircraft) Regulations, 1948, all in-coming aircraft, except those plying between the British Isles, will be met by medical officers from April 1. On arrival the commander of the aircraft will report the state of health on board, and passengers will give the names of the places in which they have been during the past 14 days. Passengers showing no symptoms of an infectious disease will be given a card setting out the precautions they should observe if they fall ill within 21 days after arrival, including showing the card to their doctor. If there is any doubt about the nature of the illness, the doctor is asked to inform the medical officer of health for the area at once.

Holiday Milk for Mentally Defective Children

Milk will be available for mentally defective children attending occupation centres whole-time during the holidays. The children should attend the school centres for holiday milk distribution.

Wills

Dr. John William Hunter, of Ipswich, left £4,544; Dr. Samuel Tonge Brooks, of Bacup, Lancs., £5,109; Dr. Charles Forbes Maclean, of Balham, London, S.W., £13,590; Dr. William Grahame Cobb, of Birchington, Kent, £20,433; and Dr. John Cunningham, of Stewarton, Ayrshire, £45,614.

COMING EVENTS

Medical Research Society Lecture

The fourth Medical Research Society Lecture will be given by Dr. Geo. E. Burch, professor of medicine in the University of Tulane, on "Radio-sodium Studies in Congestive Heart Failure" at St. Mary's Hospital Medical School, Paddington, London, W., on Friday, March 19, at 5 p.m.

Rheumatic Diseases

A concentrated week-end course on the rheumatic diseases will be held at the Rheumatism Unit, St. Stephen's Hospital (London County Council), Fulham Road, S.W., on March 19, 20, and 21. The lecturers will include Prof. J. M. Mackintosh, Prof. B. W. Windeyer, Dr. Francis Bach, Dr. Grace Batten, Dr. Philip Ellman, Mr. A. G. Timbrell Fisher, Dr. David Shaw, and Dr. A. G. Signy. Sir Adolphe Abrahams will preside at the inaugural address on March 19.

Criminal Justice

A conference on criminal justice will be held on March 21, with Dr. H. Mannheim in the chair. Lectures will be given at Oxford House, Mape Street, Bethnal Green Road, E.2, on the treatment of juvenile offenders, women offenders, and men offenders. Limited accommodation and meals are available at Oxford House, to which application should be made as soon as possible.

Association of Sea and Air Port Health Authorities

The forty-ninth annual meeting of the Association of Sea and Air Port Health Authorities of the British Isles will be held at Swansea on Wednesday, Thursday, and Friday, May 12, 13, and 14. The provisional programme includes the following papers: May 12, "The Romance of the Port Health Service and of its Association," by Dr. N. Gebbie; May 13, "History of the Swansea Port," by Mr. E. V. Swallow, and "Some Experiences of a Naval Hygiene Officer 1939-47," by Surgeon Captain H. M. Willoughby, R.N.V.R.; May 14, "The Disinfestation of Ships and Cargoes," by Mr. C. P. Heywood, and "The Egyptian Cholera Outbreak, 1947," by Dr. R. Barrett. Afternoon visits will be arranged at a later date. The honorary secretary of the association is Dr. H. C. Maurice Williams, Health Department, Civic Centre, Southampton.

Society of Chiropodists

The annual convention of the Society of Chiropodists will be held in London on Thursday, Friday, and Saturday, April 22, 23, and 24. The proceedings will be officially opened at Friends House, Euston Road, N.W., by Sir Alfred Webb-Johnson, President of the Royal College of Surgeons of England, on April 22, at 2.30 p.m.; and will be followed, at 3 p.m., by a lecture by Mr. N. C. Lake on "Surgery in Vaso-spastic Conditions of the Leg and Foot." On April 23, at 11 a.m., Prof. F. Wood Jones, F.R.S., will deliver a lecture at the Royal College of Surgeons of England (Lincoln's Inn Fields, W.C.) on "The Emergence of Man"; and on April 24, at 9.30 a.m., at Friends House, Dr. Reginald T. Brain will speak on "Common Skin Diseases affecting the Feet and Nails." There will be a reception by the president of the society and Mrs. Hanby at the Savoy Hotel on April 23, from 7 to 7.30 p.m., followed by a dance, buffet supper, and cabaret. Admittance to all lectures and functions will be by ticket only, and applications must reach the secretary of the society at 21, Cavendish Square, London, W.1, by April 1.

Edinburgh Refresher Course

A fortnight's refresher course at Edinburgh University begins on Monday, May 3, at 9 a.m. It is intended primarily for demobilized medical officers (Class II) and for insurance practitioners. Fee for graduates not claiming expenses from Government sources, 10 gns.

C.M.F./M.E.F. Physicians Reunion Dinner

The reunion dinner of the C.M.F./M.E.F. Physicians will be held at the Apothecaries' Hall, Black Friars Lane, Queen Victoria Street, London, E.C., on Saturday, April 10. Anyone interested should communicate with the honorary secretary, Dr. A. Willcox, 66, Harley Street, London, W.1.

Buckston Browne Dinner

The Buckston Browne Dinner of the Harveian Society of London will be held at the Royal College of Surgeons of England, Lincoln's Inn Fields, W.C., on Thursday, June 17.

American Meetings

The Third Inter-American Cardiological Congress will be held in Chicago at the Michael Reese Hospital on June 13-17. This will be followed on June 18-19 by the Annual Meeting of the American Heart Association, and by the meeting of the American Medical Association during the week beginning June 20. Inquiries should be addressed to the Secretary of the Third Inter-American Cardiological Congress, Michael Reese Hospital, Chicago, Illinois, U.S.A.

SOCIETIES AND LECTURES

Monday

EDINBURGH CLINICAL CLUB.—At B.M.A. Scottish House, 7, Drumhugh Gardens, Edinburgh, March 15, 8 p.m. *Business Meeting* (Current Affairs).

HUNTERIAN SOCIETY.—At Talbot Restaurant, London Wall, E.C., March 15, 7 for 7.30 p.m. Dinner-meeting. "Neuritis." Discussion to be opened by Dr. Philip Ellman, Dr. Alden Turner, Mr. Dudley Buxton, and Dr. F. S. Cooksey.

Tuesday

CHADWICK TRUST.—At the Sir Edward Meyerstein Lecture Theatre, Westminster Hospital Medical School, 17, Horseferry Road, Westminster, S.W., March 16, 2.30 p.m. "Adulteration of Food and its Detection," by J. R. Nicholls, D.Sc., F.R.I.C.

EUGENICS SOCIETY.—At Burlington House, Piccadilly, London, W., March 16, 5.30 p.m. "Mental Health Survey in a Rural Population," by Dr. W. Mayer Gross.

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—March 16, 5 p.m. *Pathological Demonstrations* by Dr. I. Muende.

INSTITUTE OF LARYNGOLOGY AND OTITIS, 530, Gray's Inn Road, London, W.C.—March 16, 5.15 p.m. "Injuries of the Ear," by Mr. E. D. Davis.

ROYAL PHOTOGRAPHIC SOCIETY.—At 16, Prince's Gate, London, S.W., March 16, 7 p.m. "Stereoscopy," Lecture by Prof. D. Harris.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL, University Street, Gower Street, London, W.C.—March 16, 4.30 p.m. Sydney Binger Memorial Lecture "Pulmonary Oedema," 17th Bernal Lecture by Prof. G. R. Cameron, D.Sc., F.R.S., F.R.C.P.

UNIVERSITY COLLEGE LONDON: DEPARTMENT OF PHYSIOLOGY, Gower Street, W.C.—March 16, 5 p.m. "Some Aspects of General Physiology," by I. E. Bayliss, Ph.D.

Wednesday

HARVEIAN SOCIETY OF LONDON.—At 26, Portland Place, London, W., March 17, 8.30 p.m. Harveian Lecture. "Alcoholism and Abstinence Realization," by Prof. Th. Alajouanine.

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION.—At B.M.A. House, Tavistock Square, London, W.C., March 17, 8.30 p.m. Discussion: "Juvenile Delinquents," to be opened by Dr. John Bowlby, Dr. Dorothy Makepeace, and Mrs. Madeline Robinson, J.P.

ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE, 23, Portland Place, London, W.—March 17, 3.30 p.m. "Postural Defects in Childhood and Adolescence" (illustrated), by Dr. F. S. Cooksey.

ROYAL MICROSCOPICAL SOCIETY.—At B.M.A. House, Tavistock Square, London, W.C., March 17, 5 p.m. for 5.30 p.m. Ordinary meeting. "Application of the Barnard Ultra-Violet Light Technique for the Study of Living Cells," by Dr. R. J. Ludford; "New Development in Visual Light Microscopy," by Mr. J. Smiles, A.R.C.S.

Thursday

BRITISH INSTITUTE OF RADIOLOGY, 32, Welbeck Street, London, W.—March 18, 8 p.m. Presidential Address: "The Place of Physics in the Training of the Medical Radiologist," by Prof. G. Sierd.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.—At Royal Army Medical College, Millbank, London, S.W., March 17, 7.30 p.m. Laboratory meeting of the Society. Various demonstrations will be given.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL, Hyde Park Corner, S.W.—March 18, 4.30 p.m. *Neurological lecture-demonstration*, by Dr. A. Feilberg.

STAINCLIFFE COUNTY HOSPITAL, Heald's Road, Don'tbury.—March 18, 8 p.m. "Some Aspects of Dermatological Treatment," by Dr. J. T. Ingram.

WELLCOME HISTORICAL MEDICAL LIBRARY: UNIVERSITY AND RESEARCH SECTION, LIBRARY ASSOCIATION: MEDICAL SUB-SECTION.—At Royal College of Surgeons, Lincoln's Inn Fields, London, W.C., March 18, 6.30 p.m. "Some Literary Surgeons," by Mr. V. Zachary Cope.

Friday

FACULTY OF RADIOLOGISTS.—At Royal Society of Medicine, 1, Wimpole Street, London, W., March 19, Joint meeting with British Institute of Radiology and Section of Radiology of Royal Society of Medicine. Symposium on *Diagnostics of the Alimentary Tract*, 2.30 p.m. (a) "Diagnostics of the Oesophagus," Operators: Dr. A. S. Johnstone and Mr. A. L. d'Abreu. (b) "Diagnostics of the Stomach, Duodenum and Small Bowel," Operators: Dr. R. Fawcett and Mr. Harold Edwards. 8.30 p.m. (c) "Diagnostics of the Large Bowel," Operators: Dr. J. L. A. Grant and Prof. Charles Wells. A discussion will follow.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—At Leeds General Infirmary, March 19, 8.30 p.m. "Diseases of the Anal Canal and Rectum," by Mr. C. Neuman Morgan.

ROYAL INSTITUTE OF PHILOSOPHY.—At University Hall, 14, Gordon Square, London, W.C., March 19, 5.15 p.m. "Truth," by Prof. A. J. Ayer.

ROYAL SANITARY INSTITUTE.—At Town Hall, Manchester, March 19, 10 a.m. "Public Health Planning," Paper by Prof. A. Tetting.

Saturday

KENT PAEDIATRIC SOCIETY.—At the Star Hotel, Maidstone, March 20, 2.30 p.m. "The Maladjusted and Delinquent Child."

APPOINTMENTS

The Committee of Privy Council for Medical Research have appointed Harold Percival Himsforth, M.D., F.R.C.P. (Professor of Medicine in the University of London), to be a member of the Medical Research Council.

After being educated at King James's Grammar School, Huddersfield, Prof. Himsforth studied medicine at University College Hospital, where he qualified in 1928, obtaining the University Gold Medal. He proceeded M.D., again with Gold Medal, in 1930, and was elected F.R.C.P. in 1938. He gave the Goulstonian lectures for 1939 and has published numerous papers including many on diabetes mellitus.

John Cecil Wilson McIhven, M.R.C.S., L.R.C.P., has been appointed deputy chairman of the Prison Commission.

Dr. J. F. Fraser has been appointed the first full-time medical officer of health for Pontefract, Knottingley, Featherstone, and the Osgoldcross Rural District.

Michael Kremer, M.D., B.Sc., F.R.C.P., has been appointed honorary assistant physician to the National Hospital, Queen Square.

DELANEY, PATRICK J., M.B., B.Ch., D.P.H., Medical and Organizing Secretary of the Medical Association of Eire.

ESHER, F. J. S., M.B., Ch.B., D.P.M., Psychiatrist, Sheffield Regional Hospital Board.

FRASER, A. M., M.D., D.P.H., Senior Administrative Medical Officer and Secretary, Scottish Northern Regional Hospital Board.

GARLAND, HUGH G., T.D., M.D., F.R.C.P., Physician in Charge, Department of Neurology, General Infirmary at Leeds.

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, London, W.C.—*Part-time Out-patient Medical Registrars:* Dorothy W. Wells, M.B., Ch.B., M.R.C.P., D.T.M.&H.; J. J. Kempton, M.D., M.R.C.P., D.C.H.

LENNOX, MARY, M.B., B.Ch., D.P.H., Port Medical Officer, Barry, Glam.

NOTTINGHAM GENERAL HOSPITAL.—*Honorary Assistant Consultant Psychiatrists:* I. J. Davies, M.D., D.P.M., and H. Fisher, M.D., D.P.M. *Medical Specialist:* R. Gwyn Evans, M.B.E., M.D., M.R.C.P.

RAEBURN, H. A., M.D., F.R.C.P.Ed., Senior Administrative Medical Officer, Scottish South-Eastern Regional Hospital Board.

ROGERS, K. B., M.D., Clinical Pathologist, Children's Hospital, Ladywood Road, Birmingham.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Armin.—On Feb. 29, 1948, at Bath, to Dr. Margaret Armin, wife of Dr. Richard Armin, a daughter.

Davies.—On March 4, 1948, at Woking, to Betty (née Benjamin), wife of Lieutenant A. Michael Davies, R.A.M.C., a son.

Milton.—On Feb. 24, 1948, at Walbrook, Banehory, Kineardineshire, to Dr. Jane Crystyan (née Salkeld), wife of Dr. David Milton, a daughter.

Ronchetti.—On Feb. 28, 1948, at Nuffield House, Guy's Hospital, London, S.E., to Sylvia (née Helme), wife of Dr. John Ronchetti, a son—John Kirkland.

Scott.—On March 3, 1948, at Nuffield House, Guy's Hospital, London, S.E., to Esmé (née Pascall), wife of Dr. Leslie Scott, a daughter.

DEATHS

Amdor.—On Feb. 22, 1948, at Royal Infirmary, Cardiff, Alfred Amdor, M.B., Ch.B., D.P.H., aged 40.

Badenoch.—On Feb. 22, 1948, at Hermon Hill Hospital, Wanstead, William Minty Badenoch, M.B., Ch.B.

Bowes.—On Feb. 25, 1948, at "Winhill," Manchester Road, Wilmslow, Cheshire, Paul Bowes, M.D.Ed.

Hurlock.—On Feb. 25, 1948, at Horsebrook House, Calne, Wilts, James Cecil Burton, M.R.C.S., L.R.C.P.

Cahalane.—On Feb. 20, 1948, Michael John Cahalane, M.B., Ch.B.Glas., Squadron Leader, R.A.F.V.R., aged 55.

Clarke.—On Feb. 24, 1948, at Hove, Joseph John Clarke, L.R.C.P.I., D.P.H., aged 86.

Dawes.—On Feb. 21, 1948, at Edenbridge, Kent, Christopher Dering Dawes, M.R.C.S., L.R.C.P., Lieutenant-Colonel, late I.M.S., aged 75.

Durran.—On Feb. 22, 1948, at Edinburgh, Donald Edward Durran, M.B., Ch.B.Ed.

Gardner.—On Feb. 27, 1948, at "Coombehurst," Church Stretton, Shropshire, Henry Willoughby Gardner, M.B.E., M.D., F.R.C.P., aged 86.

Hunter.—On Feb. 24, 1948, at Hutton House, Chilton, Ferry Hill, Co. Durham, Matthew Hunter, M.B., Ch.B.Glas.

Laing.—On Feb. 27, 1948, at 5, Princes Street, Arbroath, David Laing, T.D., M.D., aged 86.

McLean.—On Nov. 30, 1947, at Sydney, N.S.W., Leonard Allen Windsor McLean, M.B., Ch.B.

McVean.—On Feb. 26, 1948, at 24, Forest Road, Bournemouth, W., John Duncan McVean, M.B., C.M.Glas., aged 88.

Martin.—Recently, at 11, Waterloo Avenue, North Strand Road, Dublin, Conor Martin, M.B., B.Ch.

Mathias.—At Burry Port, Idwal James Mathias, M.B., B.S., aged 33.

Pilliet.—On Feb. 14, 1948, at a Nursing Home, Folkestone, Mary Amelia Pilliet, M.B., Ch.B., of Wingate Villa, 210, Canterbury Road, Folkestone, Formerly Assistant Medical Officer, London County Council.

Pollard.—On Feb. 25, 1948, at Royal Halifax Infirmary, Percy Lund Pollard, M.B., Ch.B., of East Lea, Lea Avenue, Halifax, aged 66.

Rivers.—On Feb. 28, 1948, at Redruth, Cornwall, Charles Henry Rivers, M.D., M.R.C.P., aged 76.

Rogers.—On Feb. 25, 1948, Alford Rogers, L.R.C.P.&S.Ed., of Montrose, Sewardstonebury, E., and late of Highams Park, Chingford, E.

Smith.—On Feb. 28, 1948, at Ashfield Park, Clogher, Co. Tyrone, N. Ireland, Henry Smith, C.I.E., M.D., M.Ch., M.A.O., Lieutenant-Colonel, late I.M.S., retired, aged 90.

Tavendale.—On Feb. 28, 1948, killed in a car crash, William John Tavendale, M.B., Ch.B., aged 32.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their question which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Killing Habits of Leopards

Q.—In this area (Nigeria) a leopard society is active, and often have to decide at post-mortem examination whether death was due to human or animal killing. I should therefore like to know: (a) How does a leopard usually kill, and what mark would be expected? (b) What part of the body is a leopard likely to eat first? (c) Will leopards eat intestines when muscle (of leg, etc.) is present? (d) Is it possible for a leopard to sever skin to simulate an incised wound?

A.—The leopard, like the lion, hunts by night, but, whereas the lion usually hunts in company and only when hungry, the leopard hunts alone and displays a greater inclination toward hunting and killing for their own sake. He is likely to lie in wait, probably in a tree, from which he springs down on his victim. At the moment of impact the claws sink in to establish a grip, from which there is little or no chance of release and the teeth are plunged into the neck, either at the back or front, depending on the readiness of access. Possibly the victim's throat will be torn out, and the blood drunk as it flows from the wound. Thereafter the leopard, like the lion and a number of other animals, will show a preference for the entrails of the victim, to which access is obtained by tearing open the abdomen with claws and teeth. The muscular portions of the body are likely to be ignored. The body will be dragged into cover for the latter part of the leopard's activities. This summary of the killing habits of the leopard is based on opinions expressed by Mr. T. H. Gillespie, F.R.S.Ed., F.Z.S. It supplies most of the details requested and also goes a long way towards answering the basic question, which may be paraphrased as follows: How is one to form an opinion on whether a killing has resulted from a genuine attack by a leopard or from an attack by men endeavouring to simulate the work of a leopard?

As in a variety of other medico-legal problems, it seems probable that the answer may depend at times not only on the post-mortem findings but on the fullest possible investigation of all the available evidence, including the identity of the victim, the presence or absence of motive, the time and place of the killing, signs of disturbance or human activity at the locus, signs of dragging, etc. No doubt the men of a leopard society may at times be extremely sedulous in their efforts, and for this reason such seemingly important details as the presence of claw-fragments or leopard's hair might not be conclusive evidence. The demonstration of specific saliva stains would probably be impossible or impracticable. Certain of the wounds produced by a leopard might undoubtedly resemble incised wounds, but the presence of true incised wounds would be strongly suggestive of some other agency. It is improbable that "leopard men" can avoid all inconsistencies and discrepancies which are detectable if looked for carefully. The opinion of the doctor may be an important factor in assisting the investigating authorities in coming to a decision, but it is unlikely to be the only one. Conversely, the doctor should acquaint himself with all possible information on the case before making his examination and forming an opinion.

In an interesting book entitled *Human Leopards*, by K. J. Beatty (Hugh Rees, Ltd., London, 1915, now out of print), the activities of leopard societies in Sierra Leone are discussed, and accounts given of a number of trials which took place there in 1912 and 1913. Apparently a three-pronged knife was sometimes used to simulate the claws of a leopard, but in spite of this and of the fact that the murderer(s) might wear a leopard skin, it does not seem that the methods employed ever bore any very baffling resemblance to a true leopard killing.

Penicillin for Blepharitis

Q.—How should penicillin be administered, for how long, and in what dosage in a case of blepharitis which fails to respond to routine treatment with sodium bicarbonate lavage and ung. hydrarg. oxid. flav.?

A.—Patients with blepharitis are usually either under- or ill-nourished. Attention to the general health is therefore a first consideration. Lavage with sodium bicarbonate and the application of ung. hydrarg. oxid. flav. is not a particularly good method of local treatment. It is best to avoid lotions of any kind, as they only make the skin sodden; ung. hydrarg. oxid. flav. is an unsatisfactory medicament, as many people are sensitive to mercury and, moreover, this ointment is unstable and frequently contains highly irritating products of decomposition. Any local treatment of blepharitis requires the removal of crusts before the application of ointments. Crusts are best removed by washing them off with pledgets of cotton-wool soaked in hydrogen peroxide, 10 vol., or olive oil. The lid margins should then be dried and either painted with liquor tincturiorum or covered with a thin film of penicillin ointment containing 1,000 units of crystalline (not commercial) penicillin per gramme, the base being a mixture of petroleum jelly and liquid paraffin, 90 and 10 parts of each respectively. The application of liquor tincturiorum has the disadvantage that the lid margins are deeply stained. If the application is made only at night most of it washes off with the morning toilet. Penicillin ointment should be used three or four times a day. Blepharitis generally responds to either of these methods of treatment within two to four weeks. Recurrences are, however, likely unless attention is paid to the general health. There is no need for systemic penicillin treatment.

Chronic Suppurating Bone Cavity

Q.—In the local treatment, apart from surgery, of a chronic suppurating bone cavity would the local application of penicillin and a sulphonamide powder relieve in some degree the offensiveness associated with the discharge?

A.—A chronic suppurating bone cavity usually becomes valled-in by sclerotic and poorly vascularized bone, in the depths of which the infecting organisms can remain safe from the influence of chemotherapeutic agents, whether they be applied locally or systemically. The cavity may contain an equestrium which similarly harbours the offending organisms. Moreover, the bacterial infection often becomes a mixed one, and may include organisms which are either naturally immune to chemotherapeutic drugs or which have acquired a resistance to them. These factors unfortunately minimize the possibility of significantly diminishing the offensiveness of the discharge simply by the local application of penicillin and a sulphonamide powder. Nevertheless there could be no harm in trying the effect of such applications, in the hope that by altering the bacterial flora the nature of the discharge might be modified. In cases unsuitable for surgical treatment the odour associated with the discharge can be largely overcome by enclosing the affected part, whether encased in plaster or not, in a bag or leevé made from special filter cloth. This is a coarse material impregnated with carbon particles. Its use was described by Jeddou and Florey (*Lancet*, 1942, 1, 755), and it has subsequently been found of value in the above type of case.

Secondary Signs of Syphilis

Q.—Are mucous patches of the mouth and pharynx more common in cases in which the primary sore arose on the lip rather than the genital area? I would be grateful if you could quote me any specific authority on the subject.

A.—Doubtless mucous patches in the mouth are commoner when the primary chancre is on the lip than when it is on the genitals, since lip chancres are often undiagnosed till secondary signs appear. There is, however, no reason to suppose that the site of the chancre determines the occurrence of mucous patches, since these lesions are "secondaries" and correspond to rashes of the skin; they are merely evidence of generalization of the infection and of the spirochaetes acting on epithelium. The writer knows of no specific authority on the subject, but the explanation seems obvious when the pathology of the condi-

tion is considered: spirochaetes do not cause mucous patches by being transmitted direct from the primary lesion, but by being carried to the mucous membranes in the general circulation.

Pemphigus Vegetans

Q.—What is the right treatment for a case of pemphigus vegetans? Is the disease incurable and always fatal? Is "stovarsol" by mouth of any value, and, if so, in what dosage?

A.—Pemphigus vegetans is usually fatal. Sometimes it responds to unfiltered x-ray therapy in small dosage and to sulphonamides by mouth. Suramin ("antryptol," I.C.I.) intravenously, 1 g. weekly, may control pemphigus, including pemphigus vegetans. The arsenicals are usually disappointing, but stovarsol has been recommended by M. Oppenheimer and D. Cohen (*Arch. Derm. Syph.*, Chicago, 1943, 47, 40-2) in a dose of 0.5 g. half an hour before breakfast on the first day, followed by 0.75 g. for the next two days; then three days' rest, after which treatment is resumed, dosage being reduced and intermissions lengthened. The drug should be stopped if there is pruritus or other ill-effect.

Cataract

Q.—(a) Is it best to leave a cataract unoperated upon as long as the sight of the other eye is fairly good? (b) Is there any danger in allowing a mature cataract to become hypermature, and will an operation in such a case ultimately be essential? (c) After a successful operation, can the sight of the eye be so corrected by lenses as to enable reading to be undertaken with fair results and without undue discomfort or strain? Would it be possible to drive a motor-car provided that the sight of the other eye remained fair?

A.—(a) As a good working rule a patient much prefers 6/12, even with a glass, in an unoperated eye which still has some power of accommodation to 6/6 in an aphakic eye with no such power of adjustment. It is impossible to use an operated and an unoperated eye together and so regain binocular vision unless a contact glass is fitted to the aphakic eye. Having regard to the fact that such a glass can be worn on an average only for four hours in the twenty-four, and that many cataract patients are incapable of the manipulation required in putting in and taking out the glass, it is practicable in but few cases. The advantage of regaining the temporal field of vision or what was the blind side is sometimes outweighed by an annoying diplopia. Where the cataract is obvious there is cosmetic gain from its removal. All these points must be considered before an operation is performed.

(b) A hypermature cataract may very occasionally be ruptured and the lens material escape into the anterior chamber and cause an irritative iritis. Otherwise it is unnecessary to operate.

(c) After a successful operation the patient, provided the eye is healthy, can see 6/6 and J1 easily. Reading can be sustained for long periods without strain. So long as the patient can read a number-plate at the prescribed distance there is nothing to prevent him from driving a car. There are many people driving to-day with only one effective eye.

Lichen Planus

Q.—Can you throw any new light on the aetiology of lichen planus, and what is the latest treatment?

A.—Nothing very new has been found regarding lichen planus, but there is a growing body of opinion that associates it with an infective agent, possibly a virus. A number of clinical features support that conception, including a resemblance to warts, the occasional zosteriform distribution, the occasional onset after the fashion of pityriasis rosea, and its development in affections originally diagnosed under one of these labels. The provocation of lichen planus by metallic and other drugs and by emotional shock is a further point of resemblance, but no actual virus has been demonstrated. Attempts to cure patients by filtrates made from ground lichen lesions have given indifferent results.

There is no specific therapy, and arsenic and mercury and, more recently, calciferol have their advocates. In the main

the course of lichen planus is suggestive of a psychosomatic disorder, and response to treatment seems often to relate to psychological factors rather than to any particular method of treatment.

Swelling in Boy's Breast

Q.—What is the differential diagnosis and treatment in the case of a boy aged 14, in perfectly good health, who has been referred to me in connexion with a small swelling in the upper half of the right breast? There is no pain or tenderness on pressure, but what appears to be a tiny cyst can be felt. It seemed to be a case of simple adolescent mastitis, but some question has been raised as to the possibility of new growth.

A.—The description of the swelling in this boy's breast makes the diagnosis of adolescent mastitis almost certain. The possibility of growth is so remote at this age that in the absence of fixity or accompanying glandular enlargements it can be disregarded. Presumably the effect of rubbing from braces or of other trauma has been excluded. Firm strapping and patience are all that are required in the way of treatment, but if pain is present a course of short-wave diathermy may prove beneficial.

Dextro-amphetamine Sulphate

Q.—Some proprietary tablets are now on the market the active ingredient of which is dextro-amphetamine sulphate. This drug is of value as a cerebral stimulant; have you any information about the dangers of its use? Is it a habit-forming drug?

A.—There is no reason to think that dextro-amphetamine has essentially different properties from ordinary amphetamine sulphate, or that the dangers attaching to its use, especially the danger of addiction, are more serious. However, it has not been prescribed widely enough or for long enough for anyone to be sure about this. The danger of addiction with amphetamine sulphate is very small, as there is no tendency to develop tolerance with prolonged use. Accounts have been published of a few patients, all of psychopathic personality, who have taken 50 or 60 mg. daily over prolonged periods; and the psychiatrist sees, very rarely, a toxic confusional psychosis brought on by such a heavy dosage self-administered. There are also a relatively large number of persons who habitually take small doses of amphetamine (5 to 20 mg. daily) for minor nervous symptoms, apparently without ill effect. As a general rule habitual takers can discontinue the drug without much in the way of deprivation symptoms. It may be assumed that the same considerations will apply to the dextrorotatory preparation.

Nocturnal Frequency in Elderly Men

Q.—Nocturnal frequency of micturition is very common in elderly men. This does not appear to be associated always with an enlarged prostate gland. What other causes produce it, and what can be done about it?

A.—Nocturnal frequency in elderly men is usually associated with the existence of residual urine, even although per rectum the prostate is not felt to be enlarged. The residual urine should therefore be tested by the passage of a catheter under scrupulously aseptic conditions. The most frequent other causes are infection and polyuria, due to such a condition as granular kidney.

Organisms in Nose and Throat

Q.—A routine swabbing recently gave the following result: "*Streptococcus viridans* predominant; no haemolytic streptococci isolated; right and left nostrils, pure growth of *Staph. aureus*." Is the presence of *Str. viridans* in a mother a potential danger to her child? Is it just a normal inhabitant? What treatment would you advise, if any?

A.—*Str. viridans* is a normal inhabitant of the mouth and pharynx, and is likely to be found in culture from a tonsillar swab in any healthy person. The presence of *Staph. aureus* in the nose, on the other hand, although common, is a morbid condition (pathogenicity being assumed, the best evidence of which is a positive coagulase test). Such nasal carriers can infect patients under hospital conditions (producing, for

example, pemphigus in infants and surgical sepsis). Presumably the same sort of thing can happen in ordinary life, and if there are special reasons for safeguarding the health of a particular child the condition might be treated by the insufflation of sulphathiazole.

NOTES AND COMMENTS

Treatment of Chilblains.—E. H. writes: In the answer to "Treatment of Chilblains" ("Any Questions?" Feb. 14, p. 330) I did not see this simple remedy mentioned. I find that both my own and my family's chilblains are cured by two or three exposures to an artificial sunlight lamp applied locally to hands and/or feet. We usually need one course about November when the cold weather starts, and often have to repeat it in January.

Persistent Hiccups.—Col. N. J. C. RUTHERFORD (Farnham, Surrey) writes: I am interested in Dr. J. D. Laycock's letter (Feb. 21, p. 378). Though not wounded in battle I underwent a major operation for cholecystitis in Guy's Hospital during 1933. The condition was complicated by old adhesions and entailed a good deal of pulling about. In 24 hours I started to hiccup and kept it up for eleven days. All the well-known remedies were tried, including CO₂, atropine, morphine, posture, etc. I could eat light meals and sleep when doped, but the moment I awoke I was off again hiccuping. Finally a sailor son insisted on trying a couple of liqueur glasses of Bols, a Dutch aniseed liqueur. Being the eleventh day, this treatment acted as a charm and stopped the hiccups. The late Mr. Fagge, who did the operation, informed me afterwards in his cheery fashion that "he had never seen a fellow hiccup so long and get over it. But he always felt sure that I would survive!" Nobody thought of hyoscine—or pincappie juice.

Noah Morris Memorial.—We are informed that a committee has been convened for the purpose of having erected a students' memorial to the late Prof. Noah Morris, of the Department of Materia Medica, Glasgow University. The committee represents the Students' Representative Council, both Unions, G.U.A.C., the two University medical societies, and *Surgeo*—the University medical journal. In view of Noah Morris's high reputation as an outstanding teacher and his keen interest in student affairs it is felt that present and past students taught by him would like to contribute to the memorial. Will those who would like to do so please send donations to the Clerk to Council, Glasgow University Students' Representative Council, Pearce Lodge, The University, Glasgow, W.2. Cheques should be made payable to the Students' Representative Council.

Absence of Orgasm.—Dr. JOAN MALLESON (London, N.W.) writes: I think the reply given under this heading (Feb. 28, p. 426) is somewhat incomplete as it stands. A partial or complete vaginal anaesthesia is an exceedingly common hysterical condition and by no means limited to the obviously "neurotic" woman. Inhibition of feeling can include the clitoris too; it is sometimes total, but more commonly partial, in which case the absence of final orgasm can be very frustrating. It is true that some cases of frigidity are secondary to inadequacy or precipitancy on the husband's side (if so, this fact should have been given in the case history), yet even so, if there were no intrinsic inhibition such a wife would have achieved orgasm—sleeping or waking—during the ten years of marriage. In the average case of vaginal anaesthesia it can be detrimental to imply that the fault lies with the husband, for this may be quite untrue and will inevitably cause the husband to feel baffled and hopeless and the wife to feel critical. Fortunately some cases achieve a considerable degree of improvement during the course of life, and an infinitely small proportion of such cases seek psychotherapeutic help, which may relieve them. Perhaps because there is so little effective therapy for this disorder there is a natural tendency for the patient and physician, and even the old-fashioned sexologists, to search for physical or marital explanations. The former are almost non-existent, and with careful history-taking the husband's contribution can usually be fairly accurately assessed. The physician can at least help by advising about dyspareunia, inadequate lubrication, etc., and by explanation and reassurance.

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Antilegion, Western, London*. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: *Brimedads, Western, London*. MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association, TELEPHONE: EUSTON 2111. TELEGRAMS: *Medisecra, Western, London*. SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY MARCH 13 1948

British Medical Association

SPECIAL REPRESENTATIVE MEETING

The Special Representative Meeting of the British Medical Association will be held at B.M.A. House, Tavistock Square, London, W.C.1, on Wednesday, March 17.

MOTIONS AND AMENDMENTS OF DIVISIONS

THANKS TO COUNCIL AND HEADQUARTERS STAFF

Motion by NUNEATON AND TAMWORTH: That this Special Representative Meeting before proceeding with the business of the day places on record its gratitude on behalf of the whole medical profession to Dr. Dain and the other members of the Council for their untiring efforts, especially during the past three months, in addressing meetings of Divisions and otherwise making known the important matters at stake in the Health Service to be set up by the Act of 1946. It also congratulates Dr. Hill and the Headquarters Staff on the efficient manner in which they have carried out the duties falling to them and especially in the difficult task of keeping in touch with members in all branches of the profession.

NATIONAL HEALTH SERVICE ACTS, 1946 AND 1947, AND ACCEPTANCE OF SERVICE

Motion by the CHAIRMAN OF COUNCIL that the following recommendation be adopted:

That the Representative Body, reaffirming the whole-hearted desire of the medical profession for a comprehensive health service available to everyone, urges that in the public interest such changes should be made in the Acts of 1946 and 1947 as are necessary to maintain the integrity of medicine and to prevent doctors being turned into State servants, with harmful consequences to patient and doctor alike. The Representative Body therefore expresses the hope that the Government will make it possible for the profession to co-operate by making such changes and states its view that it is not in the best interests of the public or of medicine for members of the profession to enter the Service until such changes are made.

Amendment by NOTTINGHAM: That the following be submitted for the Council's recommendation: (1) That the Representative Body reaffirms the whole-hearted desire of the medical profession for a comprehensive health service available to everyone, and

(2) That the provisions of the National Health Service Acts, 1946 and 1947, are detrimental to the interest of the public and the medical profession alike, and that it is not in the interests of either for the profession to enter the Service under the conditions laid down therein, and

(3) That the Government be urged to make such changes in the Act as are necessary in order to enable the medical profession to enter the Service freely and with good will.

Amendment by GREENWICH AND DEPTFORD: That the following be substituted for Council's recommendation:

The profession having emphatically expressed their opinion through the plebiscite that they would not enter into service under the Acts of 1946 and 1947, the Special Representative Meeting expresses the hope that the Government will forthwith introduce legislation to amend the Acts, so that the medical profession can provide an efficient health service for the people.

Amendment by OXFORD: That for the words "whole-hearted desire of the medical profession for" there be substituted the words "acceptance of the medical profession of."

Amendment by CITY OF EDINBURGH: (i) That after the word "everyone" in line 4, there be inserted the words "declares its willingness to co-operate with the Government and to reopen negotiations through its representatives with a view to the establishment of such a service, but"

(ii) That for the words "integrity of medicine" there be substituted "independent status of medicine."

(iii) That after the word "Government" in line 11 there be inserted "and Parliament."

Amendment by CLEVELAND: That after the words "patient and doctor alike" there be added "In view of the attitude of the present Minister of Health to doctors and the Representative Body, it is obvious that he will never have the confidence of the profession."

Amendment by MARYLEBONE: After the word "co-operate" in line 12 insert the word "willingly."

Amendment by GUILDFORD: That the following words be added to Council's recommendation:

That, in view of the recent B.M.A. plebiscite result, which expressed a 90% disapproval of the National Health Act in its present form, the Representative Body, whilst agreeing with a comprehensive health service available to everyone, requests that it should be postponed until the necessary hospitals have been built and equipped, and the personnel for a complete service have been trained.

Rider by BRADFORD: If the profession is to co-operate in a comprehensive service the essential freedoms must be preserved.

RESOLUTIONS RELATING TO FUTURE SETTLEMENT

Motion by CARDIFF: That the ownership of goodwill by the practitioner, abolition of basic salary and of direction, and the right of appeal to the Courts, be regarded as essentials in any settlement with the Minister.

Motion by SOUTH-WEST ESSEX: (1) This meeting is strongly of opinion that ownership of practice goodwill and the abolition of basic salary are the two issues of fundamental importance for the successful independence of general practitioners.

(2) In the event of negotiations being resumed between the Minister and the B.M.A. and/or following amendment of the Act to the satisfaction of the Negotiating Committee and the Representative Body, it is the desire of the Representative Body that neither Consultants nor General Practitioners should agree to such terms till both sections of the profession are mutually satisfied with them.

Motion by OXFORD: (1) That this meeting considers that the presence of the basic salary element of remuneration is the most important single item in the National Health Act, 1946, which may eventually lead to a salaried State medical service, and instructs its representatives to support any measures which are advised, either to eliminate the basic salary element or to ensure that it will not be used to bring about a fully salaried service.

(2) That in the opinion of this meeting the disposal of the goodwill of general practices should remain in the hands of the profession and not pass into those of the Government.

Motion by READING: That except where special circumstances justify it, the remuneration of general practitioners should be by capitation payment in proportion to the number of persons on a doctor's list and that this principle, which the R.B. regards as fundamental, should be embodied in the Act.

Motion by CITY OF ABERDEEN: That the Representative Body should now ask the Negotiating Committee to offer to

reopen negotiations with the Minister with a view to securing above all else that the principle of payment of general practitioners by capitation only should be established by statute.

Motion by CITY OF ABERDEEN: That service should be accepted by the profession only when the terms of the whole service including Consultants and Specialists are known.

Motion by EAST NORFOLK: That no final solution of differences with the Minister is acceptable, unless it contains a clause that there be no alteration in the terms of service except in agreement with the freely elected representatives of the profession.

Motion by LEIGH: That terms and conditions of service having been satisfactorily arranged should not be altered by Regulation alone, but only after discussion, negotiation, and agreement with representatives of the profession.

Motion by PLYMOUTH: That the Act be amended to guarantee freedom of expression to doctors in all matters relating to the clinical and administrative aspects of the National Health Service in which they are engaged.

APPROACH TO PRIME MINISTER

Motion by BIRMINGHAM CENTRAL: That the Negotiating Committee should approach the Prime Minister forthwith with a view to reopening negotiations.

Motion by READING: That in view of the fact that the medical profession is sincerely anxious to procure the best possible medical service for the country and that all suggestions, which they consider essential amendments to the Health Act, have been regarded as efforts to extort concessions for their own benefit; and that general practitioners have been threatened with heavy financial loss if they do not enter on July 5 a service to which they conscientiously object—this meeting suggests that the Council of the B.M.A. approach the Prime Minister with a request that appointed representatives of the profession may meet a Cabinet Committee to discuss outstanding differences, in the hope that all our energies may be once more directed to constructive effort instead of controversy.

POSTPONEMENT OF SERVICE

Motion by HARTLEPOOL: That the implementation of the National Health Service Act (1946) be postponed *sine die* and that the British Medical Association draw up in outline a scheme of medical service which would be good for the nation and could be carried out.

Motion by READING: That the suggested arrangements for the correction of maldistribution of doctors (except that of financial inducement to under-doctored areas) should be suspended for two years—and be reviewed at the end of that time.

Motion by CITY OF EDINBURGH: That in so far as the medical profession believe that a complete health service cannot be made available to everyone in July 1948 because of lack of staff and other facilities, it is suggested that particular consideration be given to the possibility of introducing the service by stages as this becomes possible.

ADVICE TO PRACTITIONERS

Motion by CARDIFF: That to ensure uniformity of action, the Association be asked to give immediate and concrete guidance on the procedure to be followed by all practitioners

(a) When approached individually by the Minister with an invitation to join the Service;

(b) When approached by members of the public to be accepted on a new National Health Service List.

Motion by GLOUCESTERSHIRE: That this meeting calls on the Council of the British Medical Association to instruct doctors how they shall act when patients present them with the new medical cards for their signature.

Motion by SUNDERLAND: That the Representative Meeting should determine new methods whereby practice may be carried

on in a satisfactory manner should the Minister insist on introducing the National Health Act, as it now stands, on the appointed day.

Motion by SOUTH-WEST ESSEX: In the event of Council's instruction being that we should refuse service after July 4—no certificates of incapacity should be issued by those practitioners not taking part in the Service.

Motion by CHESTERFIELD: That practitioners who feel impelled, for any reason, to take service under the National Health Act should be asked to give an undertaking that they will refuse to accept panel patients now on the lists of doctors who have refused service, or the dependants of such patients, unless or until a general settlement has been reached.

Motion by EASTBOURNE: That the Council should make a statement on current reports that certain persons, who are in favour of the Act in its present form, are advising patients not to enrol with any doctor who is opposed to the Act in its present form, and indicate the appropriate course of action to be followed by any doctor in these circumstances.

ALTERNATIVE SCHEMES

Motion by GUILDFORD: That in the event of a complete deadlock persisting between the profession and the Government, the Council be instructed to draw up and submit to the profession an alternative scheme based upon the 1944 S.R.M. motion by Marylebone, December 5, 1944.

Motion by GLOUCESTERSHIRE: That it is desirable that a comprehensive statement be made by the British Medical Association as to the form of a National Health Service acceptable to and approved by its members. In view of the shortage of personnel and hospital beds throughout the country, an opinion should be expressed as to when such a service could be expected to function adequately.

PRESENTATION OF THE PROFESSION'S CASE TO THE PUBLIC

Motion by HARROGATE: That this meeting urges the immediate necessity of putting the doctors' case more clearly before the general public by every possible means with greater force than hitherto has been the case.

Motion by SUNDERLAND: That a simple statement of the doctor's position be placed before the general public at once and that this statement should be followed up by an intensive publicity campaign.

GENERAL

Motion by BIRMINGHAM CENTRAL: That as this is a fight for freedom which cannot be conducted by appeasement or kid-glove methods the Representative Body should press for withdrawal of certification prior to July 5.

Motion by PLYMOUTH: That the appointment of medical representatives to bodies set up for administration of the Act should only be made after agreement with the elected representatives of the profession.

Motion by PLYMOUTH: That this meeting is of opinion that the profession should stand by the position as revealed by the plebiscite results.

Motion by BIRMINGHAM CENTRAL: That the Minister having agreed to accept the Spens Report on remuneration for general practitioners, the proposals for payment to doctors in his statement to the profession should be referred to that Committee for their consideration.

Motion by GREENWICH AND DEPTFORD: That the profession, having expressed its view emphatically through the plebiscite, this Special Representative Meeting instructs the Council not to be influenced by any "Quislings" however exalted they might be.

Motion by BRADFORD: That there should be adequate provincial representation on the proposed London Liaison Committee, and that the new Committee so formed should represent all consultants.

Motion by PRESTON: That this Meeting recommends that in addition to an advisory capacity the Central Health Services Council be granted executive power.

Motion by SOUTH-EAST ESSEX: That this meeting strongly deprecates the abusive comments made by the Minister of Health in Parliament upon our democratically elected representatives.

Motion by SOUTH-EAST ESSEX: That this meeting expresses its confidence in the Council and the Representative Body, and endorses the policy of the Association during the negotiations with the Ministry of Health.

Motion by GLOUCESTERSHIRE: That Council be instructed to approach the British Dental Association and other ancillary health services in order to establish a common front with all those who are in opposition to the National Health Service Act, 1946, in its present form.

Motion by OXFORD: That this meeting affirms its confidence in the deliberations of the Representative Body, and believes that any recommendation they may make will be based on fair and reasonable discussion.

Motion by MARYLEBONE: In view of the continued misleading statements made by the Minister of Health and supported by some sections of the Press, this meeting wishes to place on record its opinion that the British Medical Association is thoroughly representative of the medical profession and that the Council and the Representatives on the Negotiating Committee could not be elected more fairly or freely.

Motion by SOUTH BEDFORDSHIRE: That this meeting reaffirms the fact that the opposition of the medical profession to the National Health Service in its present form is not connected with parliamentary party politics.

INDEPENDENCE FUND

Motion by EASTBOURNE: That the Council should give the profession some indication of the amount it wishes to be subscribed by individual members of the profession and should state whether this should be in the form of a cash donation or a guarantee.

Amendment by SOUTH-EAST ESSEX: That the Independence Fund be based on guarantees and contributions, and that, if the guarantors be called upon, only 20% be payable in the first instance.

Motion by CLEVELAND: (1) That all other funds be merged in the Independence Fund.

(2) That contribution to the fund should be on the basis of 10% in cash, the remainder by guarantee.

(3) That, subject to the maintenance of a fighting fund, the remainder be available to young practitioners wishing to buy a share in practice, and that the interest thereon should not exceed 1/2%.

Motion by GLOUCESTERSHIRE: That in the event of moneys coming from sources outside the profession, these shall be placed in a separate fund.

Motion by GLOUCESTERSHIRE: That Headquarters should create machinery by which, in the event of a dispute, each district can be kept informed as to what is happening in its own and other districts.

Motion by HUDDERSFIELD: That the Representative Meeting be asked to suggest a suitable form of voluntary pledge or undertaking to be entered into by members meeting in informal groups in any particular district.

Motion by BUCKINGHAMSHIRE: That this meeting requests the B.M.A. and the Insurance Acts Committee to proceed forthwith with the preparation of bonds between practitioners to ensure a united front, which bonds should be put into use in the event of the Council of the B.M.A. advising practitioners to decline service.

MEDICAL MEMBERS OF REGIONAL HOSPITAL BOARDS AND LOCAL EXECUTIVE COUNCILS

Amendment by MARYLEBONE: That medical members of Regional Hospital Boards and local executive councils be requested to continue their membership, for the time being, of these bodies.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar.

Non-County Borough Councils.—Dartford, Radcliffe (limited to future appointments), Tottenham, Wallisend.

Urban District Councils.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Portlady, Redditch (restricted to new appointments), Tyldesley.

Scottish Burghs.—Motherwell and Wishaw.

B.M.A. LIBRARY

The following books have been added to the Library:

- Ackerman, L. V., and del Regato, J. A.: Cancer. 1947.
Bamford, T.: Poisons. Second edition revised by C. P. Stewart. 1947.
Bancroft, F. W., and Pilcher, C. (Editors): Surgical Treatment of the Nervous System. 1946.
Beaumont, G. C.: Medicine. Fifth edition. 1943.
Behrend, M.: Diseases of the Gallbladder and Allied Structures. 1947.
Binger, C.: The Doctor's Job. 1946.
Boyd, W. C.: Fundamentals of Immunology. Second edition. 1947.

The Home Office announces that Dr. James Cunningham, whose registered address is Abbey Street, Ballyhaunis, Co. Mayo, is no longer authorized under the Dangerous Drugs Acts to be in possession of or to supply dangerous drugs.

Association Notices

ELECTION OF MEMBERS OF COUNCIL

Notice is hereby given that nominations of candidates for election as members of Council 1948-9 (a) by the following Branches, (b) by Public Health Service members, and (c) by women members must be forwarded in writing so as to reach me not later than Saturday, April 17, 1948.

Twenty-two Members by Branches in Great Britain and Northern Ireland

	No. of Members of Council to be Elected by Group
Group A.—North of England	1
Group B.—East Yorks; Yorkshire	1
Group C.—Isle of Man; Lancashire and Cheshire	2
Group D.—Derbyshire; Leicestershire and Rutland; Lincolnshire; Nottinghamshire	1
Group E.—Bedfordshire; Cambridge and Huntingdon; Essex; Hertfordshire; Norfolk; Northamptonshire; Suffolk	1
Group F.—Berks, Bucks, and Oxford; Birmingham; Staffordshire	1
Group G.—North Wales; Shropshire and Mid-Wales	1
Group H.—South Wales and Monmouthshire	1
Group I.—Metropolitan Counties	4
Group J.—Bath, Bristol, and Somerset; Gloucestershire; Worcestershire and Herefordshire	1
Group K.—Dorset and West Hants; South-Western; Wiltshire	1
Group L.—Southern; Surrey	1
Group M.—Kent; Sussex	1
Group N.—Aberdeen; Dundee; Northern Counties of Scotland; Perth	1
Group O.—Edinburgh; Fife	1
Group P.—Glasgow and West of Scotland (Glasgow Division)	1
Group Q.—Border Counties; Glasgow and West of Scotland (Five County Divisions); Stirling	1
Group R.—Northern Ireland	1

Public Health Service Members

Two members of Council are nominated and elected by members of the Association employed in the Public Health Service as defined in By-law 1 (3). Candidates must be members of the Public Health Service as so defined.

One Woman Member

One woman member of Council is nominated and elected by women members of the Association.

Nominations

The nominations must be on the prescribed forms, copies of which can be obtained on application to me. A notice will be published by the Council in the *British Medical Journal* (Supplement) on May 8, 1948, of the candidates nominated. Where contests occur, voting papers will be issued on May 15, 1948, containing the names of all duly nominated candidates, from the Head Office, British Medical Association, Tavistock Square, London, W.C.1, to each member in the Group, or to the Public Health Service members, or to women members. A notice will be published by the Council in the *Supplement* of June 5, 1948, giving the results of the elections where there have been contests.

CHARLES HILL,
Secretary.

Diary of Central Meetings

MARCH

- 16 Tues. Special Conference of Local Medical and Panel Committees, 11 a.m.
- 17 Wed. Special Representative Meeting, 10 a.m.
- 24 Wed. Council, 10 a.m.

Branch and Division Meetings to be Held

CLEVELAND DIVISION.—At St. Luke's Hospital, Middlesbrough, Thursday, March 18, 2.30 p.m. Clinical demonstration of Modern Psychiatric Methods followed by a tour of the Hospital.

EAST HERTS DIVISION.—At County Hospital, Hertford, Thursday, March 18, 9 p.m. Address by Mr. R. Rowden Foote: A Practical Survey of Varicose Problems. The address will be preceded by a report on the Special Representative Meeting on March 17.

GREENWICH AND DEPTFORD DIVISION.—At Chiesman's Restaurant, 33, Lewisham High Street, London, S.E., Thursday, March 18, Annual Dinner and Dance.

HYDE DIVISION.—At Dukinfield Town Hall, Wednesday, March 17, 8.30 p.m. Dr. George Fletcher: Some Healing Cults.

SOUTH ESSEX DIVISION.—At Oldchurch Hospital, Romford, Friday, March 19, 9 p.m. Clinical meeting. (1) Medical film on Government Scheme for Rehabilitation; (2) Clinical Address by a member of the Staff.

SUNOERLAND DIVISION.—At Sunderland Royal Infirmary, Friday, March 19, 7.45 p.m. Clinical demonstration by Messrs. J. M. H. Ross and J. A. Weir; Address by Prof. A. A. Gemmel: Some Aspects of Domiciliary Midwifery.

TUNBRIDGE WELLS DIVISION.—At Kent and Sussex Hospital, Tunbridge Wells, Clinical Week-end Meeting. Saturday, March 13, 2.30 p.m., Dr. Evan Bedford: Hypertensive Heart Disease; 3.45 p.m., Mr. F. A. Williamson-Noble: Eye Emergencies in General Practice; 5 p.m., Prof. Chassar Moir: Post-Partum Haemorrhage and Obstetric Shock; 8.45 p.m., Dr. Gordon Masefield: Common Sense Psychiatry. Sunday, March 14, 10.45 a.m., Prof. Henry Cohen: The Diagnosis of Backache; 12 noon, Mr. W. M. Mollison: The Acute Ear; 2.15 p.m., Dr. A. C. Roxburgh: Skin Diseases in General Practice; 3.30 p.m., Mr. A. Lawrence Abel: Some Common Diseases of the Rectum and Anal Canal (with cinematograph film). Fee for lectures £1 ls. Sunday, March 14, 5 p.m. At Kent and Sussex Hospital, Tunbridge Wells, Special Divisional Meeting. Instruction of Representatives for Special Representative Meeting on March 17.

WESTMINSTER AND HOLBORN DIVISION.—At City Hall, Charing Cross Road, London, W.C., Thursday, March 18, 8 p.m. Agenda: To hear reports by the Representatives on the Special Representative Meeting held on March 17.

Meetings of Branches and Divisions

METROPOLITAN COUNTIES BRANCH

The first of a series of five lectures arranged by the Metropolitan Counties Branch for medical students and newly qualified practitioners was given by Sir Crisp English at B.M.A. House on Nov. 4, 1947. Dame Louise McIlroy presided. Dr. A. French, Hon. Sec. of the Branch, welcomed a large audience. Sir Crisp English took "Patients" as his subject. He pointed out that the best possible results for the individual patient could be achieved only by a study of human nature, aptitude in handling a sick man's mind, and the application of common sense, combined with modern technical treatment. He quoted Sir Frederic Treves, who used to say: "Always explain matters to your patient in simple easily understood language; if you cannot do this, you may be sure that you do not understand or grasp the facts of the case yourself. Medicine is common sense." The doctor must be a good listener, and it was important that he should be able to deal with anxious relatives. The lecturer went on to discuss the range of ages of surgical patients, the need for early post-operative rising, and the different approach called for in the case of mothers, fathers, sons, daughters, and young children. Elderly patients presented special problems, particularly when operation was necessary. Sir Crisp English continued with some account of medical men, scientists, lawyers, and business men as patients, and concluded his lecture with a list of the things that a doctor should not do.

Prof. F. A. Maguire, of Sydney, then described the special difficulties of practice in Australia, and Dr. E. A. Gregg, President of the Metropolitan Counties Branch, moved a vote of thanks to the lecturer.

H.M. Forces Appointments

ROYAL NAVY

Temporary Surgeon Lieutenants (R.N.V.R.) J. M. Cliff and P. D. A. Durham have been transferred to the Royal Navy.

ROYAL NAVAL VOLUNTEER RESERVE

Surgeon Lieutenant-Commanders T. Colver and H. R. Vickers, V.R.D., have been placed on the Retired List.

Temporary Acting Surgeon Lieutenants R. Graham, R. Dwyer, A. P. Cornwell, S. K. Earner, J. P. Finnegan, D. A. Macfarlane, and D. E. E. Jones to be Temporary Surgeon Lieutenants.

ARMY

Major-General E. A. Sutton, C.B., C.B.E., M.C., K.H.S., late R.A.M.C., has retired on retired pay.

Colonels A. C. Jebb, and J. H. G. Hunter, late R.A.M.C., having completed four years in the rank, are retained on the Active List supernumerary to establishment.

Colonel C. O. Shackleton, late R.A.M.C., having attained the age for retirement is retained on the Active List supernumerary to Establishment.

Colonel G. D. Harding, late R.A.M.C., has retired on retired pay.

Lieutenant-Colonel T. B. H. Tabuteau, from R.A.M.C., to be Colonel.

HOUSEHOLD CAVALRY, R.H.G.

War Substantive Surgeon Captain P. R. Westall, from Emergency Commission, to be Surgeon Captain.

BRITISH MEDICAL JOURNAL

LONDON SATURDAY MARCH 20 1948

EPILEPSY*

BY

Sir CHARLES SYMONDS, K.B.E., C.B., D.M., F.R.C.P.

Physician for Nervous Diseases, Guy's Hospital

Now and again in the history of medicine the invention of a new instrument suddenly lights up the path of clinical observation so that many things which have been seen dimly, become clear. Speculation is replaced by knowledge, which in turn shows the way to further speculation. Thought advances at a bound. At such a moment it may be forgotten that had it not been for all the patient and careful examination of what had already been seen this advance could never have been made, and that further progress must still depend upon clinical observation, helped, but not replaced, by the new method. The electroencephalogram (E.E.G.) has thrown a light into many dark places on our way to the knowledge of epilepsy, but I would remind you at the outset that although the existence of an abnormal discharge of energy in the cerebral cortex coincident with epileptic attacks has only recently been proved by electrical methods, Hughlings Jackson seventy years ago conceived the idea that such a discharge must be the basis of epilepsy, and his views have been accepted by neurologists since that time as the basis of further speculation.

One of the ways in which the E.E.G. has helped the neurologist is in testing clinical hypothesis. For example, a man aged 30 came to me in 1947 with the story of two recent generalized epileptic attacks. There was a family history of epilepsy. The patient also complained of twitching in his eyes, which had gone on continuously since he could remember. This symptom was easily observed, for it occurred two or three times in every five minutes. The eyelids closed briskly but not so completely as to prevent one seeing an associated upward movement of the eyeballs. The whole episode lasted about a second. This complaint had been diagnosed as a tic or habit spasm, but it was not quite like a voluntary movement. Incomplete closure of the eyes as a voluntary movement is not associated with visible upward movement of the eyeball. Considered in its setting the symptoms suggested an epileptic discharge for this reason, and I made a note that I thought it must be epileptic though I had never seen a case with such frequent, circumscribed, and stereotyped motor expression. There, before the advent of the E.E.G., the observation would have ended in suspicion without proof. The electrical record showed a typical epileptic discharge with each episode of blinking. Confirmation in a case of this kind is of great value, for we have all many times seen little attacks in which the diagnosis has been doubtful, and with increasing experience we have all probably become less inclined to exclude epilepsy as the cause, because we have continued

to observe new and sometimes quite peculiar variants happening, at first alone, but later as the aura of an undoubted fit. Now we have at least the chance of getting confirmation, though a negative record would still leave doubt, for in these very brief myoclonic episodes there may be no detectable electric discharge.

Epileptic Variants

There are many variants of epilepsy of whose nature we can be sure without the aid of the E.E.G., but which because they depart so far from the "ordinary" attack are apt to escape recognition. I suppose that loss of consciousness with or without convulsive spasm is the criterion most widely used in practice for the diagnosis of epileptic attacks. It is not sufficiently appreciated that in many attacks consciousness is not lost but disturbed. The sufferer may be aware of all that is going on around him, may hear and understand what is being said, but is for the time being unable, as he says, to collect his thoughts or reply to a question. There is in fact not loss of consciousness, but confusion, which may be of the mildest degree. As Gowers put it, the effect of an epileptic attack upon the stream of consciousness may vary from a complete interruption of its flow to a mere ruffling of the surface.

Apart from convulsive spasm there may be a momentary loss of power, and on the sensory side a great variety of abnormal feelings constituting the epileptic aura, which may occur without disturbance of consciousness. The chief characteristic of all these slight attacks is their suddenness and brevity. It would be impossible here to attempt any classification of epileptic variants. I shall select one or two for example.

First, the attacks called myoclonic. Anyone who has witnessed a generalized convulsion will have observed that sometimes after this is over there is occasional twitching of the limbs, which may continue for a while after the patient has regained his senses. Myoclonic twitching of this type often precedes an epileptic attack, and it may be the only symptom of an attack. Usually it is confined to the arms, and is especially apt to occur during the first hour or two after waking. There is no disturbance of consciousness, but sudden jerking movements of one or both arms which may interfere for the moment with dressing or shaving. The experienced patient knows when this happens that he may have a fit, but quite often the myoclonus passes off without this. The movements are fractions of a generalized convulsion. In rare instances such myoclonic twitching may be the only evidence of

*Annual oration to the Harrogate Medical Society, 1947.

epilepsy in a patient who never has any generalized convulsion or disturbance of consciousness, and may occur with great frequency

Next let me take a rare form of attack. Ramsay Hunt (1922) noted many years ago that a patient might sometimes fall without any disturbance of consciousness at all. Recognizing the epileptic character of these attacks, he called them "drop seizures." I have met with several examples of this kind of attack, and two families in which several members were afflicted. I recently saw a married woman of 62 whose only complaint was of falling attacks. These she had had since the birth of her first child when she was 26. They tended to occur in series at long intervals, and she had had five in as many weeks before I saw her. All were exactly the same. They occurred only when she was standing; without warning and without any impairment of consciousness she fell to the ground, as a rule forwards on hands and knees, often bruising herself. She was immediately able to get up without assistance. These attacks were never precipitated by laughter or other emotion, being thus distinguished from the well-known phenomenon of cataplexy. Her mother, who died at 65, had exactly similar attacks during the last ten years of her life, and an older sister also has them.

Focal Symptomatology

All these peculiar phenomena of the epileptic attack should, I think, be classified under the heading of focal symptoms because symptoms which are so specific must be related to the site of maximal epileptic discharge. This was the conception of Hughlings Jackson, derived from clinical observation long before modern methods had provided opportunity for precise observation. Seeking proof to support his theory, he found a case in which convulsive spasm in a single limb was associated with a sear in the appropriate area of cortex due to a depressed fracture. Hence the extraordinary notion that Jacksonian epilepsy and traumatic epilepsy were the same thing. Jackson used a case, which happened to be traumatic, to prove his argument that a lesion of a particular part would cause a particular kind of attack. To anyone who reads his papers it must be perfectly clear that this was all he meant. He was concerned with the localization of the lesion, not with its pathology. He was well aware that focal symptoms might occur in cases of brain tumour, or in what is called idiopathic epilepsy. Dr. James Collier used to say that the commonest cause of a Jacksonian attack was idiopathic epilepsy—a broad generalization which I believe is true when the idiopathic attacks are accurately observed, for there is very often an initial symptom of the attack which indicates a focal origin.

Penfield's (1946) observations in recent years have enriched our knowledge of focal symptomatology. With painstaking accuracy he has recorded the effects of electrical stimulation of different areas of cortex in patients subjected to craniotomy under local analgesia. His experiments have confirmed in the most striking way many of the conclusions reached by Hughlings Jackson from clinical observation. Jackson, for example, first described two kinds of attack associated with lesions of the anterior temporal lobe—the hallucinatory attack of taste or smell, and what he called the dreamy state. Penfield was able to produce both kinds of attack by stimulation of the anterior temporal cortex and of no other part of the brain. These attacks therefore have great localizing value, and the descriptions given by patients are characteristic. The smell or taste is always the same, always unpleasant, never quite like any normal taste or smell. The dream, which may include both hallucinations and illusions, has the dreamlike com-

bination of unreality and familiarity. In many cases both of organic disease and of idiopathic epilepsy Penfield was able to reproduce by stimulation attacks which the patient recognized as the same as those which happened spontaneously.

From what I have said you will appreciate that when we recognize a focal origin for the attack this does not imply an organic basis. Nevertheless the story of focal attacks in a patient with idiopathic epilepsy is usually different from that of a patient with a cerebral tumour and the difference seems to depend upon the existence in idiopathic epilepsy of an abnormal state of the cortex as a whole, which makes it easier for the epileptic discharge to spread. The focal attack of idiopathic epilepsy may remain focal if the discharge is a slight one, but a more severe discharge will tend to spread. Consequently the patient often has minor attacks which consist of nothing but what we call an aura; but if there is a major attack consciousness is lost and convulsion, if it occurs, is generalized. By contrast, the discharge from an organic lesion is often restricted whatever its degree. The patient may have focal convulsions or sensory phenomena of considerable extent and rapid recurrence with no loss of consciousness or generalized convulsion. Such attacks recurring in stereotyped form usually indicate a coarse lesion—most often, of course, a tumour.

Modern Methods of Pathological Diagnosis

The preliminary sifting is made from the clinical data. Fits beginning under the age of 20 in those with a positive family history are idiopathic unless there is some strong clinical evidence to the contrary. The same is true of fits beginning in this age period which have continued for several years even though the family history is negative. But when we meet with a recent history of fits in an adolescent with negative family history and clinical examination, a radiograph of the skull is worth while. It is a simple procedure, and now and again will reveal some gross abnormality. For example, an otherwise healthy girl of 16 had a single fit with generalized convulsion and loss of senses. The onset was with spitting as if she wanted to get rid of something unpleasant—suggestive of a temporal lobe focus. Clinical examination was negative, and there was no family history of attacks. The radiograph showed a calcified tuberculoma in the right temporal lobe.

In adults the onset of the fits demands more detailed investigation. Past head injury, middle-ear or sinus infection, encephalitis, and cerebral syphilis are uncommon but important causes, and anyone who has lived in India should have the limbs x-rayed for evidence of cysticercosis. Radiographs of the skull should be done as a routine—calcification is quite common in the gliomas, which are the commonest of cerebral tumours. The E.E.G. is useful, and doubtless when apparatus is available will be considered indispensable. In 50% of idiopathic epileptics the record is of positive diagnostic value, and in another 25% it shows abnormalities which are suggestive. An organic lesion if fairly near the surface shows focal slow wave activity. An air encephalogram completes the investigation. Useful information can be obtained by the injection of 30 c.cm. by lumbar puncture—a procedure which as a rule upsets the patient only for a day or two. If epilepsy is symptomatic of a removable tumour (meningioma) there will very probably be a filling defect, though normal pictures are compatible with an infiltrating glioma. No one quite knows how many of the patients without apparent hereditary or other cause starting to have fits in adult life eventually prove to have tumours. It is commonly estimated at 50%.

Natratss (1943) has questioned this belief on the basis of a follow-up of 81 cases whose first attack was after the age of 40, finding that of 57 who could be traced 16 had died in less than twelve years, but only nine of proved organic cerebral disease. The course in the others, both dead and survivors, had been that of idiopathic epilepsy. My impression is that his figures, though small, are near the truth. A considerable number of idiopathic epileptics have their first attack after 30, and idiopathic epilepsy is a very common disease.

Causation

About the causation of idiopathic epilepsy we have much still to learn, but the E.E.G. has taught us a good deal about the hereditary factor. Its familial incidence has of course been long recognized, though in only about a quarter of the cases, and then curiously enough more often in siblings, aunts, and uncles than in either parent; but Lennox and the Gibbss (1940) have recorded the following observations. They examined E.E.G. of 183 first-degree relatives of 94 patients with clinical epilepsy and found abnormal E.E.G.s in 60% as compared with 10% of 100 persons with no personal or family history of epilepsy. In 53 instances records were obtained from both parents, and in only 5% were both normal. Even more startling was the finding that in 35% both parents showed an abnormal E.E.G. Of the relatives with abnormal E.E.G.s only 1 in 3 had clinical epilepsy. Lennox and his collaborators conclude that the abnormal E.E.G., presumably associated with an epileptic tendency, may be inherited as a dominant trait. The risk of an epileptic offspring having epileptic children is great only if the mate also carries the trait. Thus if a person with epilepsy will choose a mate who has a normal brain rhythm his chance of having any offspring with epilepsy is greatly reduced. His chances of normal offspring are greater than those of parents both of whom have no present or family abnormality but have brain waves of abnormal frequency.

The E.E.G. has therefore become an indispensable aid to the doctor who is asked for advice about the risk of inheritance by a person about to marry who has a personal or family history of epilepsy. The answer is that if the proposed mate has no personal or family history of the disease and has a normal E.E.G. the risk is negligible.

It is fairly safe to assume from the available data that the most important cause of idiopathic epilepsy is an inborn liability to abnormal cortical discharge. If this is granted we still want to know what are the conditions which from time to time precipitate this discharge. We know that most people may have epileptic attacks under certain conditions—for example, extreme degrees of cerebral anoxia or hyperglycaemia—but in idiopathic epilepsy no such conditions are required. The attacks as a rule occur without any apparent cause. In a very small proportion of the cases the opposite is true—the attacks occur only with a specific precipitant. These cases of so-called reflex epilepsy form an interesting group. The best-known example probably is acusticomotor epilepsy, in which a sudden noise precipitates an attack, but there are many others. Coughing, micturition, and sexual orgasm, for instance, may be specific precipitants, or sudden contact of particular parts of the body. In this last group sometimes local contact will provoke a focal attack in the part touched, and electrical records can show the arrival of the sensory impulse in the cortex, the local epileptic discharge, and the resulting muscular contraction occurring in a time sequence corresponding with the known rate of conduction of the nervous impulse.

The artificial production of attacks in epileptics is often possible by alkalosis induced by over-breathing, or by

extreme hydration brought about by a high fluid intake and injections of "pitressin," but there is no evidence to suggest that these causes are commonly of any clinical importance.

Age is certainly important. Infants are peculiarly susceptible to fits, but it is certain that in many cases infantile convulsions are evident of an abnormal liability in this direction. The proportion of infants with convulsions who later develop epilepsy is higher than of those who have not had them: a history of infantile convulsions is commoner in epileptics than in non-epileptics; and a history of infantile convulsions is more often obtained among the relatives of epileptics than of non-epileptics: all these differences are significant and the point has an important bearing upon treatment. An infantile convulsion, especially if without adequate precipitating cause, should be the occasion for inquiry into the family history, and if this is positive regular and protracted sedative treatment should be given.

A striking feature in many cases of epilepsy is the time at which the attacks occur. They may occur only during sleep or between certain hours of the day, often during the first hour or two. A monthly rhythm is frequently noticed in women on account of the relation to menstruation, but is also to be observed in males. Periodicity of the attacks, however, may be seen at much longer intervals of months or years (Griffiths and Tylor Fox 1938). Such periods must always be looked for and taken into account in treatment. Without this it is impossible to estimate the efficacy of drugs.

Diagnosis of Epileptic Attacks

I shall confine myself here to the distinction between epilepsy and syncope, which I think may be a very difficult problem. Syncope as a rule has an obvious cause—for example, long standing, especially on an empty stomach, sudden emotion, or intense apprehension—and it is fairly safe to say that a sudden attack of falling with loss of consciousness without such a cause is not syncopal. It is not so safe to assume that an attack of this kind provoked by emotion is not epileptic. In some persons with reflex epilepsy emotion may be the precipitant, and it may be a particular kind of emotion. In a syncopal attack there is usually some warning—dimness of vision, weakness, uncertainty of balance. But this is not an absolute rule. A person may fall in a faint with little or no warning; and, conversely, a minor epileptic attack may be preceded by similar sensations. If the epileptic attack is closely observed twitching of face or hands is commonly seen—symptoms which at first might be considered diagnostic of epilepsy. But this is not true. If the cerebral anoxia resulting from syncope is severe enough an epileptic discharge with twitching is the result. The following case illustrates the difficulties of differential diagnosis.

In 1937 I saw a boy aged 13 with the history that in the previous six years he had had five attacks of unconsciousness. The first occurred when he had a tooth out with local anaesthesia, the second on getting up after influenza, when at lunch he suddenly slid unconscious under the table. The third happened when he was standing in a row of boys at school waiting to be examined by a doctor, the fourth also at school while waiting to be inoculated, the fifth when because of the recent attack he was taken to see his family doctor, who gave the following account. "While I was listening to his heart and chest I looked up at his face and noticed he was very white. He then fell. At first he was pale; his lips then became cyanosed, and at the same time I noticed twitching of fingers and hands. This lasted only a few moments; his colour then immediately returned and he got up and said he was all right." The only relevant fact in the family history was that a maternal uncle had from childhood

always fainted easily when frightened—if, for example, he saw an accident. The patient himself had had a serious head injury in a car accident at the age of 3, being severely confused for a fortnight. I decided in favour of syncope, and heard no more of him till he was 21 and an officer in the Guards.

The story then was that he had had no further attacks till he was at Sandhurst, when while listening to a lecture on first aid he had suddenly lost his senses and fallen from his seat on to the floor. A year later he had a similar attack while being medically examined. The medical officer was convinced from his observation that this was an epileptic attack and sent him to a neurologist with this diagnosis. While the neurologist was listening to his heart it suddenly slowed to a rate of about 20 a minute and then stopped for an estimated period of 45 seconds, during which the report stated "he had a fit, rolling eyes, rigidity, and a few convulsive movements." The neurological diagnosis was Stokes-Adams disease, and he was recommended for invaliding. The E.C.G. and E.E.G. were normal.

Dr. Denis Williams then staged an attack. Preparations were made for simultaneous recording of E.E.G. and E.C.G.; a rather large needle was produced and the patient was told that it would be stuck into his arm and would be painful. He at once became pale, with marked slowing of the heart beat; his lips became cyanosed and he was momentarily confused. There was no abnormality in the E.E.G. My conclusion was that these attacks were neither epileptic nor symptomatic of heart block, but severe syncopal attacks with a specific emotional precipitant. I gave considerable weight to the family history. However, I advised that he should see Dr. Parkinson, who was confident that they were not Stokes-Adams attacks but gave his opinion against the diagnosis of syncope. His arguments, which he has kindly allowed me to quote, are of great interest. "I know that in extreme instances of fainting convulsions can occur, but rarely. Ordinary faints seldom persist from age 8 to 21 years; the warning is longer, and lesser degrees are common in the same individual. You will gather that in my opinion they might be severe faints, but I incline personally to regard them as of an epileptic nature."

It is my own opinion that we have here an example of what might justly be called reflex syncope. I have met with several comparable examples, and all have had these features in common: (1) a specific liability to faint at the sight of blood, or an accident, or the account or thought of injury or illness; (2) a tendency for this liability to begin in youth and persist into adult life; (3) the occurrence in some attacks of epileptiform convulsions; and (4) a family history of similar liability.

Anticonvulsant Drugs and E.E.G.

The E.E.G. has been of a certain value in providing scientific proof of the efficiency of anticonvulsant drugs. Many patients who are subject to repeated attacks show between these attacks very frequent brief discharges on the E.E.G. which are characteristic of an epileptiform explosion. These are known as subclinical attacks, and it can be shown that their frequency can be diminished or even abolished by sufficient doses of phenobarbitone. Another interesting demonstration is the effect of concentrated mental activity in inhibiting these subclinical attacks, confirming the impression of all experienced clinicians that epilepsy is most apt to occur when the mind is empty and least when it is active and busy. Unfortunately the impression of many lay persons is the opposite, and the doctor is often expected to prescribe prolonged absence from school at the onset of epilepsy—advice which is sometimes given with harm to the patient.

The most important contribution of the E.E.G. to treatment, however, is in connexion with the new drug "tridione." The normal E.E.G. consists of a fairly regular 10-a-second rhythm of low-voltage discharges. Of all patients with clinical epilepsy 25% show rhythms within

normal limits; 50% show abnormality of an irregular kind—usually medium-voltage slow-wave activity; 25% show runs of slow- or fast-wave activity which is characteristic of epilepsy. In this group—the epileptics with epileptic E.E.G.s—there are different kinds of abnormality in the E.E.G. which corresponds roughly to different varieties of attack.

In what is clinically called grand mal—loss of senses with generalized convulsions—the E.E.G. shows bursts of high-voltage fast waves or spikes. Attacks of similar pattern but lesser degree, which the clinician might well call petit mal—brief loss of senses with widespread but slight and momentary tonic and clonic spasm—are associated with the same type of E.E.G.—i.e., the grand mal type of E.E.G. A new name is needed for these attacks, and, based upon the E.E.G. findings, the somewhat ambiguous title "minor grand mal" has been used to describe them. The term has some practical value because attacks with this type of E.E.G., whether grand mal or minor grand mal, respond on the whole better to phenobarbitone, with or without "epanutin," than to other drugs.

Another type of E.E.G. is that in which there is a series of medium-voltage flat-topped slow waves. This is found to be associated with attacks in which confusion and disordered behaviour are the outstanding features, with little or no muscular twitching. These so-called psychomotor attacks respond best to epanutin.

The third type of E.E.G. is characterized by alternating slow and fast waves of rather high voltage—the so-called wave-and-spike complex. This again is subdivided into a round wave followed by a sharp spike—the so-called dome-and-dart E.E.G.—which is characteristic of true petit mal, and a more rapid alternation of flat-topped wave and spike known by electro-encephalographers as the petit-mal variant. Of practical importance here is that if attacks are associated with the dome-and-dart E.E.G. they are likely to be controlled by tridione and are equally unlikely to be influenced by any other anti-epileptic drug. The dome-and-dart E.E.G. is invariably found in what at one time was called pyknolepsy. The main characteristics of this variety of petit mal are an onset in childhood; the daily occurrence of frequent, brief, stereotyped attacks of loss of consciousness seldom accompanied by muscular twitching, except in the face; preservation of the intellectual functions; and a relatively good prognosis. It was recognized before the advent of tridione that the attacks not infrequently ceased at puberty never to return. Other clinical varieties of what the electro-encephalographer calls a true petit mal because of the association with a dome-and-dart complex are brief myoclonic attacks and attacks in which there is sudden falling with loss of consciousness but without twitching. Lennox (1947a) has reported the effects of treatment with tridione in 166 patients with true petit mal, having the characteristic E.E.G.: 31% became entirely free from attacks, 32% had less than one-fourth the previous number; 20% improved to a lesser extent, and 17% are unimproved. By contrast, tridione given to patients with uncomplicated grand mal brought about improvement in only 20%, and actually made 50% of the patients worse. Patients with psychomotor attacks are not so often the worse for tridione, but they do not do so well as with epanutin. I have mentioned that the clinical pattern of true petit mal varies, including very brief loss of consciousness with twitching, if any, confined to the face; myoclonic twitching without loss of consciousness; and attacks of falling with momentary disturbance of consciousness. All three of these clinical variants are equally amenable to tridione. The shorter the history and the younger the patient the better the result of treatment.

Tridione is dispensed in 0.3-g. capsules. The initial daily dosage for infants is one capsule a day, for those aged 2-4 years two capsules a day, for those 5-16 years three capsules a day, and for adults three or four capsules a day. If after one month the attacks are not controlled the dose is increased by one capsule at monthly intervals until relief is secured, toxic symptoms occur, or the dose is doubled. The maximum improvement is usually in the first month, but Lennox reports the case of a child of 8 having 50 to 70 attacks a day in whom at the end of six months the dose was raised to seven capsules daily with final disappearance of the attacks.

The commonest toxic symptom is photophobia, which occurs in about half the cases. It is very seldom severe enough to require cessation of treatment, though sometimes the patient may have to wear dark glasses in sunlight. Rashes have been observed in 14% of cases treated, usually acneiform and confined to the face, sometimes generalized and like that of measles. This calls for cessation of treatment, which is begun again when the rash has subsided, starting with one capsule every other day and gradually increasing the dose to the required level. Most patients acquire tolerance. Much more important, but apparently rare, is the danger of agranulocytosis. Lennox reports three deaths from this cause, and it follows that a fortnightly white blood count is essential for all patients taking tridione. Lennox recommends that a leucocyte count below 4,000 together with polymorphonuclears less than 40% should be an indication for at least temporary discontinuance.

Social Problem of Epilepsy

The epileptic in society has not hitherto been given much sympathy or help. He is obviously disqualified from many professions and trades, but most epileptics are intelligent and normal persons apart from their attacks, and quite able to earn their living. In the U.S.A. it has been estimated that 1 in 200 of the population are epileptic, and there is no reason to suppose that the incidence in this country is less—which means that there are something like a quarter of a million persons suffering from this malady in Great Britain. Supposing half of these to be educable and employable the problem deserves special consideration not only on account of its size. A good deal has been done in America to bring the public to a sense of their responsibility in this matter. There is, however, an instinctive repugnance among healthy people not so much for the disease as for the sight of an attack, and it is for this reason that I believe schoolmasters and parents on the one hand and employers on the other may successfully resist the humanitarian appeal for the epileptic to be admitted more freely to the normal social group. More epileptic schools and self-supporting colonies therefore seem to be the answer.

One problem which most of us must have encountered is that of the epileptic who wants to drive a car, and often does so whatever medical advice may have been given. The applicant for a licence has to answer the question "Do you suffer from epilepsy?" and is told that if in doubt regarding the answer he should get professional advice. The responsibility for declaring a liability to fits clearly lies with the applicant, but it is presumably the responsibility of the applicant's medical attendant to inform him that he has such a liability. Many patients have consulted me who have had one or more epileptic attacks but as the result of treatment have been free from attacks for so long that they claim, not unreasonably, that they should no longer be considered liable to fits as applicants for a driving licence. I have sought from the Ministry of Health and from the Home Office a definition of epileptic liability for purposes

of the Road Traffic Act with no very satisfactory result. My inquiries were related to two separate cases—one that of a man whose fits had been traumatic and who after surgical removal of a bone fragment which had penetrated the dura had remained free for two years. The other patient, a young farmer, had had two attacks of the idiopathic kind. I advised regular dosage with phenobarbitone and told him on no account to stop this without seeing me again. He returned six years later, having continued regularly with his treatment, with no further attacks. Owing to the death of his father he was now in a position in which inability to drive a car was a very serious handicap.

I am informed that the Ministry of Transport in drawing up the regulations for driving licences were advised by a committee of experts appointed by the B.M.A. and were advised that "once an epileptic always an epileptic," and that any person who has at any time suffered from fits should be refused a driving licence. No legal ruling, however, was made, and the answer to my specific question in 1946 was that there is no provision in the law which defines the time which must elapse from the occurrence of a seizure before an applicant for a driving licence may be certified as not being liable to fits. "The legal department takes the view that subsequent liability under the circumstances is entirely a medical question." This to my mind is an unsatisfactory state of affairs, placing as it does an onus upon the practitioner. For his own protection he would probably be wise to inform his patients that the occurrence of a single epileptic attack is a permanent disqualification for a driving licence. This also may be the ideal advice for the protection of society, but is it practically fair? As Lennox (1947b) points out, driving accidents must be at least a hundred times more often due to chronic alcoholism than to epilepsy, but the applicant is not required to state that he has never been under treatment for alcoholism. Nor are patients with known coronary disease debarred. I have known two who have had coronary occlusion when driving, in each case resulting in a serious accident. I think it is time that legal machinery should be set up which would enable the epileptic who has been free from attacks for a specified period to state his case before an impartial tribunal. This would not only be safer to the epileptic but would also be in the public interest. I have no doubt that at present many epileptics are driving to the danger of the public who might be deterred from doing so by a law providing a specified period of freedom from attacks.

The annual report of the Institute of Child Health of Birmingham University has recently been published. The Institute attaches great importance to postgraduate training, dividing it broadly into three main types: (1) for those doctors who intend to specialize in paediatrics; (2) for general practitioners who want a refresher course; and (3) for medical men who want to specialize in administration. The Institute has received large numbers of applications from postgraduate students in Britain and abroad, and during 1947 received students from India, Palestine, Italy, Poland, Malia, and South Africa. Some of the main lines of research carried out at the Institute are outlined in the report as follows: (1) The nutrition of premature infants. This work is sponsored in part by the Medical Research Council and is being carried out at the Premature Baby Unit at Sorrento. (2) Protein digests in premature, wasted, and marasmic infants. (3) Infections in infancy—nature, reactions, and treatment. (4) Protein and fat metabolism in coeliac disease. (5) Aplastic anaemia, kernicterus, and other haematological problems. (6) Causes of stillbirth and neonatal death.

A PSYCHO-ANALYTIC CONCEPT OF THE ORIGIN OF DEPRESSION*

BY

W. CLIFFORD M. SCOTT, M.D.Tor., D.P.M.

*Director, London Clinic of Psycho-Analysis; Senior
Psychotherapist, Maudsley Hospital, London*

General interest in the psycho-analytic psychopathology of depression may have been kept in the background for a long time owing to the rapid development of interest in the psychopathological understanding of the less complex symptoms common in neurosis, such as anxieties, phobias, obsessions, etc. The psychopathology of schizophrenic symptoms, where the mechanisms sometimes seemed obvious and apparent but where the psycho-analytic treatment was not then helpful, interested more analysts in the early days than did the psychopathology of manic-depressive symptoms. Nevertheless since 1911, when Abraham first discussed depression, the psycho-analytic psychology of normal sorrow, depression, mourning, and grief, and the psychopathology of abnormal depressions have gradually developed until now concepts have been worked out which are to a considerable degree new and can be stated simply. Such new concepts have been found to be of essential value in psycho-analytic attempts at therapy and investigation of depressed states regardless of the degree of severity, regardless of the sex, and more or less regardless of the age—children as young as 2½ years and adults in the sixth decade having been treated.

The earlier work of analytic writers (Abraham, 1911, 1916, 1924; Sigmund Freud, 1917; Rado, 1927; Jones, 1929) was invaluable. The background of theoretical construction already developed was necessary to make the recent development possible. With the recent work courage was needed to make the new observations. The work done in this country in the past 15 to 20 years, chiefly by and under the stimulation of Klein, has brought much clarity to the problem of abnormal depressed states, and incidentally points the way to further work with schizophrenia. Klein published her first conclusions on this subject in 1935. She has added much to our knowledge of the technique of investigation and attempts at therapy, and has added (1940) to our theoretical constructions.

Most of the views I am putting forward are based on evidence personally obtained during the psycho-analytic treatment of neuroses with depression and with manic-depressive states in different sexes of different ages from late infancy to late life (Scott, 1946).

First Appearance of Depression

To introduce the subject a brief outline needs to be given of how the infant develops to a stage which allows depression to appear for the first time. What follows after this stage of development has been reached is the history of the different forms depression assumes at different periods of life. Just as the early stages of love and hate are significant in understanding their later development, so also may the varieties of adult depression become understood to a greater degree if we can become clearer about the genesis of depression in human life.

Regardless of different views about the source or nature of instinct, it can be said that from an early age the infant breathes air, sucks milk, passes water and stool, moves about, and sleeps. These activities are normally pleasant. If any of these activities is frustrated the infant becomes angry. Regardless of how intense or diffuse his anger may

become, regardless of how many organs he uses to vent his anger, he will first show his anger in the situation where the frustration is; for instance, if breathing is frustrated he will breathe angrily, if sucking is frustrated he will suck angrily.

From the earliest period of life one aspect of each of these pleasant or angry activities is its direction, namely, the direction of movement or interchange between what can be called the outer and the inner worlds, or the direction of interchange between this inner world and the outer world—for instance, breathing in, breathing out, swallowing in, vomiting out, etc.

Only slowly in the developing scheme of things are "people" as the adult knows them included. Earlier the world consists of what adults would call "parts"—breasts, faces, hands, etc. Only slowly in the scheme of things does a "self" as a "whole person" or "other people" as "whole people" develop. Only slowly do distinctions between what are later called perceptions, memories, images, etc., arise. Along this line of development crucial points can be discovered, and it appears that at one of these crucial points depression becomes possible for the first time. Previously only simpler affects, such as anger, pleasure, pain, fear, etc., are possible. It is in relationship to the manner in which these early depressive feelings arise and are dealt with that we can see the hope of understanding the symptoms of later depressions and understand how they can be dealt with. It is here that we see the beginnings of the development of normal tolerance of depression, of normal ways of dealing with depression, and also the beginnings of pathological depressed states.

"Good" and "Bad"

Let us follow some of these early sequences in greater detail. Hunger may lead to sucking a breast or breast substitute and to pleasure. Through the feelings of breathing, sucking, smelling, touching, swallowing, etc., the feeling of a "good something" going into or entering the inner world occurs. Technically this something is customarily referred to as an "object." During or following such an experience the child may pass water or stool or sleep with pleasure without as yet clearly appreciating with the same clarity as it later will that there is "a something" or "an object" associated with the experience of evacuation. Nevertheless he is already beginning to realize that an interchange between the outer and the inner world and between the inner world and the outer world is occurring. The general feeling of an infant feeding and later evacuating and sleeping is that both the inner and the outer world are "good" and that a "good" interchange in each direction has occurred.

On the other hand, hunger may not be followed by such a satisfying experience. Instead it may be followed by frustration and bellowing and gnashing of toothless gums, by angry movements, by passing water and stool in his rage, and so forth. This leads to the feeling that the inner and outer worlds are "bad" and that any object differentiation in the inner or outer world is into many "bad" objects, and that any interchanges between the inner and the outer world, which may have occurred in either direction, have been bad. Such a bout of anger may, of course, be followed later by satisfaction, but this type of satisfaction will be different from what it would have been had the bout of anger not preceded it. Similar experiences are repeated and repeated. The series of pleasures, frustrations, and annoyances build up memories, on the one hand, of attitudes to the inner and outer worlds in which the omnipotent infantile loving imagination has had free play, and, on the other hand, of persecutory attitudes to the outer and inner worlds in which omnipotent infantile hateful imaginations have had free play. Here much may be learned

*A paper read on Sept. 10, 1947, at a Symposium on "The Psychopathology of Depression" at the International Conference of Physicians in London.

THE SIGNIFICANCE OF HARRISON'S GROOVES

BY

J. NAISH, M.D., M.R.C.P.

Medical Registrar, Bristol Royal Hospital

AND

H. R. E. WALLIS, M.B., M.R.C.P., D.C.H.

Medical Registrar, Bristol Children's Hospital

The origin of the term "Harrison's grooves, or sulcus," has hitherto been obscure. Three standard medical dictionaries—Dorland's, Stedman's, and Gould's—attribute the eponym to Edward Harrison (1766–1838); but no account of the deformity can be found in any of his works (Edward Harrison, 1806, 1810, 1820). Dr. Charles Singer told us that because of this uncertainty Sir Frederic Still was unable to include a note on the grooves in his *History of Paediatrics*.

Samuel Gee (1870) and W. Fox (1891) both refer to Edwin Harrison's method of determining the height of the diaphragm by means of the lateral thoracic grooves, which were apparently common in the early part of the last century. In following up this clue we have been successful in exhuming the original description of the grooves.

Edwin Harrison (1779–1847), a physician to the St. Marylebone Infirmary, wrote no books and few papers. However, the pages of the *London Medical Gazette* for the years 1835–7 reveal that he was interested in the grooves as a physical sign in examination of the chest. The first inkling comes from an article by a Dr. Williams on Oct. 3, 1835. He refers to the grooves, and states that "the chief object of this communication is to announce them to the profession as original observations of my friend, Dr. Harrison, whose peculiar repugnance to authorship deters him from doing so himself." Then, in July, 1836, Clendinning (in a paper which is printed next to Marsh's original description of his test for small quantities of arsenic) gives more details and an acknowledgment to Harrison. Finally, in 1837, Edwin Harrison managed to overcome his "peculiar repugnance to authorship," and we have a note which included the following observations:

"2. On moving the hand along either side of the chest vertically, on what may be considered as the median line, it will sink into a depression corresponding to the height of the diaphragm on that side.

"3. A depression, or depressions, between the ribs can be felt or seen, or both felt and seen, at each abdominal inspiration, indicating (at least in the physiological state) the presence of the diaphragm in that part of the chest.

"... If it should turn out that my opinions are not so original as I believe them to be, I trust that I shall always be found ready to make the avowal."

Theories of Causation

The mechanism of the formation of the grooves has also remained obscure, and has been the theme of many fairy-tales told to students in their early clinical days. Rilliet and Barthez (1843) first expressed the view that the grooves correspond to the attachment of the diaphragm to the ribs, and this error has been repeated in textbooks up to the present day (Holt, 1939; Nelson, 1946; Paterson and Moncrieff, 1947). Seventeen years later Jenner (1860) pointed out that the grooves are level with the upper surfaces of the liver, spleen, and stomach, whereas the diaphragm is attached to the margins of the ribs and costal cartilages diagonally along the thoracic outlet. This observation was given publicity by Charles West (1874)

in what was for many years a standard textbook on children's diseases.

Rilliet and Barthez (1843) also postulated a gap between the attachments of the major muscles of thoracic respiration and those of the diaphragm: they suggested that the negative intrathoracic tension is in that area able to overcome muscular resistance and so produce indrawing of the ribs. Jenner (1860) was unable to find this gap. Examination of a cadaver confirms his observation. The ribs and cartilages are clothed closely in muscular attachments, and the insertions of serratus magnus interdigitate most intimately with those of the external and internal oblique muscles. Moreover, the line of insertion of serratus magnus runs diagonally across the site of Harrison's grooves.

Jenner (1860) considered that the determining cause of the deformity was atmospheric pressure, aided by the elastic contractility of the lungs. He stated that if the thoracic wall were made of cast-iron the diaphragm would descend only so fast as the air could enter the lungs. If the chest wall were soft, or if there were obstruction to the entry of air into the lungs, recession of the wall would be expected to occur. This recession would occur at the most yielding part of the wall—that is, on either side of the sternum, at the costochondral junctions, and at the anterior ends of the ribs. The abdominal viscera would prevent the collapse of the lower ribs.

Herlitz (1945) states that he has observed hiccupping in infants, and that in them reaction of the chest wall occurs at the same site as Harrison's grooves. Hiccup is due to involuntary contraction of the diaphragm, which sucks in air so suddenly that the vocal cords are drawn together. After this the negative pressure in the thorax must become very great. If further proof of the role of non-expansion of the lung be needed, try the experiment of pinching a newborn baby's nose while its mouth is kept shut. Recession of the ribs at the site of Harrison's grooves then occurs. Dupuytren (1847) noted an association between the grooves and an enlargement of the tonsils in children at the breast, but the children he described seem to have been suffering also from rickets and bronchitis. Fisher (1946) noted the development of a unilateral groove in a child suffering from pulmonary collapse following measles.

Rogers-Harrison (1842) attributed the grooves to the habit of grasping infants tightly round the chest when lifting them. Rees (1850) thought that they were due to the infant's arms being folded across its chest and bound too tightly with swaddling-clothes. McGonigle (1931) stated that they were due to the abdominal enlargement which is found in rickets pressing the lower ribs outwards.

Jenner's reasoning does not adequately explain why Harrison's grooves should develop where they do. Recession of the chest wall, according to him, should occur along the line of the costal cartilages on either side of the sternum, but in fact this type of vertical groove is commonly seen only in severe rickets, when the anterior ends of the ribs and costal cartilages are softened by disease. There must be some other explanation to account for the extremely frequent development of the transverse Harrison's grooves. Here it is necessary to refer back to the theory of the muscular gap. Although no such gap exists, it is nevertheless true that at the site of Harrison's grooves there is a neutral zone between two parts of the thorax, each moving in a slightly different direction. Thus the upper ribs move upwards and forwards, rotating outwards, while the lower ribs move outwards and backwards, increasing the transverse diameter of the upper abdomen (Johnston, 1932). It would seem likely, therefore, that increased negative intrathoracic tension would tend to cause buckling in of the chest at the hinge between these two movements rather than anywhere else.

Method of Study

The present investigations were undertaken in order to provide some factual basis for discussion, and in the hope of stimulating thought and research in the future. The full results and the analysis are given in a work already published by one of us (J. Naish, 1947).

The following groups were studied: (1) 500 children selected at random from 23 primary schools in the City of Bristol; (2) 25 children who were diagnosed as suffering from rickets eight years previously; (3) 100 children attending a clinic for asthmatics; and (4) 36 children suffering from congenital heart disease.

The depth of the grooves was measured with a home-made instrument, which was calibrated in fractions of an inch. This instrument was applied vertically to the chest at the site of the maximum depth of the groove. A light even pressure was used in order to avoid sinking the flat edges of the instrument into the skin. The width of the measuring blade prevented this from sinking into an inter-costal space and so giving a false reading. Girls at about the age of puberty could not be examined because development of the breasts interferes with these measurements.

Control Group

The 500 children, whose ages ranged from 5 to 12, were examined at routine school inspections at 23 primary schools in the City of Bristol. The incidence of the grooves is given in Table I. Analysis of the full figures showed

TABLE I.—Incidence of Harrison's Grooves in Control Group

Harrison's Grooves	No. of Children	Percentage of Total
Absent	272	54.4
Unilateral .. .	17*	3.4
Up to 3/16 in. (0.48 cm.) deep ..	177	35.4
3/16 in. or more deep .. .	34	6.8
Total:	500	

* 13 (77%) of these were left-sided. This finding contrasts with the statement that the grooves are commoner on the right side (Holt, 1939).

but there was no significant difference of incidence between males and females or between separate age groups.

A full examination was possible in only 354 of the 500 cases; in the rest (146), owing to the absence of the parents or some other cause, a satisfactory history could not be obtained. The incidence of grooves in the 354 children was not significantly different from that in the whole group (45.2% as against 45.6%).

Positive Results.—(1) Harrison's grooves occurred more often in those who had suffered from pneumonia in early life. (2) The association of the grooves with bronchitis, measles, and pertussis in early life was probable, but not statistically significant. (3) From the parents' statements it also seemed that grooves occurred more often in children who had suffered from greater degrees of upper respiratory disease (frequent colds or sore throats and ear disease) in infancy and early childhood, but this finding was not significant. (4) Grooves occurred with significant frequency in children with pigeon breasts, and in these children there was often other evidence of past rickets. (5) Grooves were found to be commoner in the children of poorer parents.

Negative Results.—(1) Breast-fed children were no less liable to develop Harrison's grooves than bottle-fed children. (2) Vitamin D fortification of diet in infancy did not reduce the incidence. (3) Neither present objective evidence of past rickets nor smallness of stature was associated with an increased incidence.

In addition the grooves occurred in a number of healthy children who had no history of previous disease.

The association with pneumonia is shown in Table II. The grooves occur more often and are deeper in those

who have had pneumonia, especially during the first year of life or on more than one occasion. The results are significant.

TABLE II.—Association of Harrison's Grooves with a History of Pneumonia

Harrison's Grooves	No Pneumonia	Pneumonia Occurred			
		At 2 Years or Over	Between 1 and 2 Years	Below 1 Year	Twice or More
Absent ..	179	10	3	1	1
Unilateral ..	9	2	0	1	1
Up to 3/16 in. deep	107	5	2	3	7
3/16 in. or more deep	17	3	0	2	1
Totals: ..	312	20	5	7	10

The social and economic conditions of the 121 children selected at random were investigated by Miss E. C. Moynagh, lady almoner at the Bristol Royal Hospital. On the basis of the average weekly income of the household during the first two years of their lives, the children have been separated into two groups, with a dividing-line at 10s. per head. The results show that grooves are more common in poverty-stricken households (Table III). The difference is significant.

TABLE III.—Association of Harrison's Grooves with Poverty

Grooves	No. with Average Income Over 10s. per Week per Person	No. with Average Income Under 10s. per Week per Person
Absent ..	37 (59.6%)	18 (30.5%)
Present ..	25 (40.4%)	41 (69.5%)

Rickets

Dr. Corner (1944) recorded the cases of a large number of children who had been diagnosed as suffering from rickets eight years previously. She kindly allowed us to examine her records, and we chose 60 children in whom the evidence of rickets in infancy had been unequivocal. Only 25 mothers were able to bring their children for re-examination. This poor response was due chiefly to population movements during the war. The results are set out in Table IV. Of the 25 children examined 16 (64%)

TABLE IV.—Evidence of Past Rickets Correlated with Depth of Harrison's Grooves

25	8	Yes	—	—	—	—	"

* Minimal = One side less than 1/8 in. (0.32 cm.) deep, but grooves present on both sides.

had grooves. A high proportion of those with deep grooves had shown either unequivocal clinical evidence of rickets in infancy or very high plasma phosphatase values, or else had been diagnosed after the age of 6 months.

In drawing conclusions from these findings it should be understood that treatment has probably modified the course of the disease, particularly where the diagnosis was made early. There are two unknown factors in each case: (1) the duration of rickets before diagnosis, and (2) the extent of bone-softening before treatment was instituted. It is tempting to postulate that the children with the highest plasma phosphatase values are those with the greatest degree of bone-softening. This is supported by the results in Table IV, but the number of children examined was too small for significant results to be obtained.

Asthma

We examined 100 children at the Bristol Children's Hospital in 1946. All were suffering from chronic bronchial asthma and were attending a special clinic under the care of Dr. Corner. There were 65 boys and 35 girls, whose ages ranged from 3 to 13. Of these 79% had Harrison's grooves, and 36% had grooves at least 3/16 in. (0.48 cm.) deep. There is a significant difference, therefore, between the incidence in this group and that in the control group. Deep grooves occurred more often in children in whom asthma developed early in life, but the difference in incidence is not significant. There was, however, a significant association between the occurrence and depth of the grooves and the duration of the asthma. This is shown in Table V. A history of pneumonia had no influence on the incidence of the grooves in these children.

TABLE V.—Harrison's Grooves and Duration of Asthma

Grooves	Duration of Asthma Less than 4 Years	Duration of Asthma 4 Years and Over
Absent	15	6
Less than 3/16 in. deep ..	18	25
3/16 in. or more deep ..	3	33
Totals: ..	36	64

(Note: We have been unable to gain access to the paper written by J. Brock in 1942 entitled "Über Pseudorachitis Asthmatica.")

Congenital Heart Disease

A. E. Naish (1945) records eight cases of congenital heart disease seen in infancy with marked inspiratory indrawing of the lower intercostal spaces. There was no evidence of rickets or upper respiratory obstruction in these children, and in only one was the heart grossly enlarged. He told us that five of them were observed for three years, and in that time three died and two developed Harrison's grooves.

We examined 36 unselected children with congenital heart disease attending Prof. C. Bruce Perry's cardiac clinic at the Bristol Royal Infirmary. The results are shown in Table VI. The numbers in each group are too small to be analysed separately, but the incidence of grooves in cases other than those of apparently uncomplicated pulmonary stenoses and of patent interventricular septa was significantly greater than in the control group.

TABLE VI.—Harrison's Grooves in Congenital Heart Disease

Grooves	Controls	Pulmonary Stenosis or Patent Interventricular Septum	Other Congenital Heart Disease
Absent	272	11	2
Present	228	12*	11*

* Including three cases in infancy with marked indrawing of lower intercostal spaces at the usual site for Harrison's grooves.

Summary and Conclusions

Reference is made to the original description of lateral thoracic grooves by Edwin Harrison.

Theories as to their causation are summarized. The theory that the grooves are caused by the insertions of the

diaphragm has been disproved several times and should be abandoned.

A study was made of a sample of 500 Bristol school-children, 25 cases of past rickets, 100 cases of asthma, and 36 cases of congenital heart disease.

Harrison's grooves occurred in 45.6% of normal school-children between the ages of 5 and 12 years. Grooves at least 3/16 in. deep were present in 6.8%. The grooves were often found in children known to have had severe rickets in infancy; on the other hand, in milder cases or cases diagnosed and treated early their incidence was not different from the normal. They occurred very frequently in children with the deformity known as pigeon breast, which is almost certainly due to severe rickets. In these children vertical grooves on either side of the sternum are often also present. Whistler (1645) noted: "At first the sternum is depressed, but as the disease progresses it projects." The conclusions reached by Dalyell and Mackay (1923) that Harrison's sulcus is valueless as an early sign of rickets has been borne out by this study; while the older observations that the grooves develop (frequently in association with a pigeon breast) in severe rickets has been substantiated.

The grooves occurred more often in children who had had pneumonia, particularly if they had suffered from the disease in the first two years of life. They also occurred frequently in children who had had bronchitis, measles, pertussis, or severe upper respiratory infections in early life, but the statistical significance of these findings could not be proved. The heaviest incidence was in children suffering from asthma, and the longer the asthma had persisted the more likely were the grooves to be present.

These results seem to support the suggestion that the most important factor in the production of Harrison's grooves is deficient expansion of the lungs.

Grooves were also frequently found in children with severe grades of congenital heart disease. The explanation of this is not clear. Sheldon's (1938) suggestion that the probable cause of indrawing of the intercostal spaces is pulmonary atelectasis occurring as a complication of the heart disease seems to fit in with the known facts, but this has not been confirmed.

We wish to express our gratitude to Prof. C. Bruce Perry for his help and advice during this investigation; to Dr. Beryl Corner for allowing us access to her cases and records; and to Miss E. C. Moynagh for her work on the social and economic conditions of some of our cases. We would also like to thank Dr. J. Brierley for advice on anatomical considerations, Dr. George Smart for assistance with statistical calculations, and Mr. G. F. Home, librarian of the Royal Society of Medicine, for helping us to find Harrison's original description.

"MYANESIN" AS A RELAXANT IN CHILDREN

BY

W. H. ARMSTRONG DAVISON, M.D., B.S., D.A.

*Clinical Associate in the Department of Anaesthesia,
Royal Victoria Infirmary, Newcastle-upon-Tyne*

$\alpha : \beta$: dihydroxy- γ -(2-methylphenoxy)-propane ("myanesin," British Drug Houses Limited) is obtainable in 10-ml. ampoules of a 10% solution. Its use as a relaxant in anaesthesia was first described by Mallinson (1947), and its pharmacology has been discussed by Berger and Bradley (1947). Unlike curare, myanesin does not appear to interfere with voluntary movements, but only with spinal reflexes, and therefore, presumably, with muscle tone. It may be suggested that its site of action is the internuncial neurones, which might account for the fact that respiration is not inhibited for long periods. Toxicity is low.

Myanesin has been used by me since February, 1947. In adults its action was not so marked as that of curare, and it was enhanced by ether and by thiopentone, while its effect was minimal when only nitrous oxide or cyclopropane was the anaesthetic used. Further, although abdominal relaxation might occur, laryngeal spasm was not prevented. It therefore seems that its use in adult surgery is limited, although it may be of value in cases in which the respiratory depression caused by curare may be a source of alarm.

Relaxation may be obtained for abdominal surgery in infants by a number of methods. Deep ether anaesthesia is open to obvious dangers; local analgesia is time-consuming, and comparatively large doses of the agent may be needed, and even then relaxation may not be perfect; spinal analgesia, while being unsuitable psychologically for children over 2 years of age, is difficult to give to younger infants, and there are obvious hazards associated with it. Curare, in my hands, has given good relaxation, but has always been associated with profound respiratory depression. This may be serious in the infant, owing to the difficulty of controlling it: closed and semiclosed methods of anaesthesia are contraindicated on account of the "dead-space," while without endotracheal intubation it is almost impossible to inflate the lungs and not distend the stomach. It is questionable whether intubation, with consequent narrowing of the glottis, is advisable in very small infants.

Myanesin was administered to 44 children between the ages of 24 days and 4½ years. The results have been satisfactory. In all cases maintenance of anaesthesia was with open ether, induction being with ether, nitrous oxide, or ethyl chloride. There were 16 cases of intussusception, 16 of

pyloric stenosis, and 12 of appendicitis, with or without peritonitis. Anaesthesia was maintained in first plane, third stage; in cases lasting up to 20 minutes it was found that one dose of myanesin sufficed, and that no more ether was required after the peritoneum had been opened. Recovery was extremely rapid, and the post-operative condition was always better than would have been expected had other means been employed. Respiratory depression lasting 15 to 30 seconds occurred in one-third of the cases; in one case respirations were completely inhibited for nearly half a minute. After the initial depression the tidal air assumed normal proportions. There were no obvious changes in pulse rate, although blood pressures were not taken. There were no deaths during operation, but two occurred after operation, in neither case ascribable to myanesin. Relaxation came on rapidly and was good for 10 to 25 minutes after injection, its extent being sometimes obscured by pre-existing distension of the bowel. Clinically, no effect upon bowel movements or tone could be seen.

The injection of myanesin was made into the intravenous drip, if one were set up, or into the longitudinal sinus at the posterior angle of the anterior fontanelle, for at this point the sinus is wider than in front and the approaching edges of bone direct the needle automatically into the vein. Blood is aspirated before injection, but it is unlikely that intrathecal injection would be dangerous. The dose was in the order of 2 ml. per stone (6.35 kg.) of body weight.

The following cases, selected from the series, illustrate the dosage and effect of myanesin in children.

Case Reports

Case 1.—Pyloric stenosis. Aged 24 days. Weight 9 lb. 3 oz. (4.17 kg.). General condition good. Rammstedt's operation. Induction and maintenance with open ether. Myanesin 1.5 ml. into the longitudinal sinus at six minutes. Slight respiratory depression for 30 seconds. Relaxation excellent and still present at the conclusion of operation at 26 minutes. Child began to cry as the last suture was inserted. No ether had been given after the peritoneum was opened. Recovery uneventful.

Case 2.—Pyloric stenosis. Aged 4 weeks. Rammstedt's operation. Induction and maintenance with open ether. Myanesin 1 ml. at eight minutes. Operation concluded at 19 minutes. Relaxation good. No respiratory depression. Recovery uneventful.

Case 3.—Pyloric stenosis. Aged 6 weeks. Weight, 7 lb. 2 oz. (3.23 kg.). Rammstedt's operation. Induction with open ether, maintenance with ether-oxygen endotracheally with Ayre's T-piece. Myanesin 0.75 ml. at five minutes. Operation concluded at 19 minutes. Relaxation poor at first (? underdosage), although there was slight respiratory depression for 15 seconds. Relaxation good during closure. Recovery uneventful.

Case 4.—Pyloric stenosis. Aged 8 weeks. Rammstedt's operation. Induction and maintenance with open ether. Myanesin 1.5 ml. into the longitudinal sinus at seven minutes. Operation concluded at 20 minutes. Relaxation excellent. Respirations completely inhibited for 20 seconds after myanesin had been given. This inhibition of respiration caused some alarm while it lasted, but there was no change in colour. When respiration was resumed it was at first rather shallow, but it became normal after a further 30 seconds. Recovery uneventful.

Case 5.—Intussusception. Aged 3 months. Weight, 11 lb. 5 oz. (5.13 kg.). Induction and maintenance with open ether. Myanesin 3 ml. at five minutes. Operation concluded at 27 minutes. No respiratory depression. Relaxation good; reduction of the intussusception intraperitoneally. Recovery uneventful.

Case 6.—Intussusception of three days' standing. Aged 4 months. Weight, 10 lb. 10 oz. (4.82 kg.). General condition fair. Intravenous drip (plasma) set up two hours before operation. Induction and maintenance with open ether. Myanesin 1.5 ml. was administered at seven minutes, with slight respiratory

depression for 30 seconds. Intraperitoneal resection of the intussusception was impossible and resection of a portion of the gut with end-to-end anastomosis was undertaken. At 38 minutes a further dose of 1 ml. was administered. Operation was concluded at 57 minutes. Only small quantities of ether were employed from time to time to maintain anaesthesia in the first plane, and the child started to cry while the skin was being sutured. Death occurred five hours later.

Case 7.—Intussusception. Aged 7½ months. Weight, 19 lb. (8.62 kg.). Induction and maintenance with open ether. Myanesin 2 ml. into the longitudinal sinus at six minutes. There was slight respiratory depression for five minutes. Operation concluded at 14 minutes. No ether was administered after the myanesin had been given. Relaxation was excellent. Recovery uneventful.

Case 8.—Intussusception. Aged 11 months. Weight, 18 lb. 8 oz. (8.39 kg.). Induction and maintenance with open ether. Myanesin 2 ml. at 13 minutes into the longitudinal sinus. Operation concluded at 33 minutes. No ether administered after the peritoneum was opened. Relaxation was excellent. Recovery uneventful.

Case 9.—Appendix abscess for 48 hours. Aged 1 year 10 months. General condition bad. Induction and maintenance with open ether. Myanesin 3.5 ml. into the intravenous drip saline at two minutes, and a further dose of 1.2 ml. at 16 minutes. Operation concluded at 32 minutes. There was no respiratory depression, but relaxation was not quite so good as usual. Death occurred from peritonitis on the fifth day.

Case 10.—Appendicitis. Aged 3 years 11 months. Induction with ethyl chloride, maintenance with open ether. Myanesin 5 ml. at three minutes. Operation concluded at 16 minutes. There was no respiratory depression. No ether was administered after the peritoneum was opened. Relaxation was good. Recovery was uneventful.

Case 11.—Appendicitis with abscess. Aged 4 years 6 months. Temperature, 103° F. (39.4° C.). Pulse, 150 before operation. Induction with nitrous oxide, maintenance with open ether. Myanesin 3 ml. at three minutes and 1.5 ml. at 23 minutes. Operation concluded at 33 minutes. Small quantities of ether were required from time to time. There was no alteration in the pulse rate during operation and no respiratory depression. Relaxation was good. Recovery uneventful.

The 44 cases to which myanesin was administered were *unselected*. The results achieved seem to indicate that relaxation in infants can be obtained with greater ease and safety with myanesin than with any method previously employed. The lack of anxiety which was felt during operation, even about patients gravely ill, is a fair measure of the success obtained with this drug.

Summary

Various methods of obtaining relaxation in children not having proved entirely satisfactory, myanesin was used with success in 44 cases. There were no deaths or post-operative complications attributable to it, in spite of the serious general condition of some of the patients. Relaxation was good and of sufficient duration to render a second dose unnecessary, save when the operation was somewhat prolonged.

The technique of administration is described, and the dosage employed in eleven cases is given in detail.

Anaesthesia was maintained in every case with ether, and it was usual to find that little or none was required after the myanesin had been introduced.

Clinical Dental Roentgenology Technic and Interpretation, by J. O. McCall, D.D.S., F.A.C.D., and S. S. Wald, D.D.S., F.A.C.D. 2nd edition, W. B. Saunders, 35s., is a comprehensive and well-illustrated book including accounts of specialized dental x-ray technique and interpretation of bony and dental pathological conditions. The latter section in particular has excellent illustrations, making it most useful for reference.

TREATMENT OF GOLD DERMATITIS BY BAL

BY

N. R. W. SIMPSON, M.B., B.S.

Supernumerary Medical Registrar, Royal National Hospital for Rheumatic Diseases, Bath

The use of BAL (2,3-dimercaptopropanol) in the treatment of gold dermatitis has been reported on in this country by Peters *et al.* (1947) and by Slot and McDonald (1947), and in the U.S.A. by Cohen, Goldman, and Dubbs (1947), by Ragan and Boots (1947), and by Lockie, Norcross, and George (1947). Its efficacy seems to be due to its ability to form relatively stable ring compounds with gold salts, thereby diminishing the reaction with the tissues and increasing urinary excretion from the system (Peters *et al.*, 1947). The following account is of its action on two cases of gold dermatitis seen recently.

Preparation and Mode of Administration.—The preparation used was 5% BAL in arachis oil, with 10% benzyl benzoate. It was administered by deep intramuscular injection into the buttock or thigh. The site of injection was subjected to light massage for a few minutes afterwards, as it was thought that this might diminish any pain and tenderness and possibly lessen the danger of inflammation and abscess formation. The dosage was 2 ml. four times on the first day, 2 ml. thrice daily for three days, 2 ml. once daily for nine days, and thereafter 2 ml. every alternate day.

Case 1

A lorry driver aged 45 had suffered from rheumatoid arthritis over a period of fifteen years. In 1942 he was given a series of gold injections (preparation and total amount prescribed unknown). After 12 injections the course had to be stopped because of the development of a rash involving both axillae, perineal and scrotal areas, legs, and trunk. He at the same time had what appears to have been a severe stomatitis. There was apparently no amelioration of the rheumatoid arthritis.

A second course of 16 injections of "myocrisin," totalling 0.985 g., was given between May 20 and Sept. 30, 1947. There was apparently a marked improvement in his primary condition, the E.S.R. falling from 123 mm. to 28 mm. in the hour (Westergren), but the patient himself noticed little change in the pain or the disability. On Oct. 7 (one week after finishing his course) a rash appeared, and on Oct. 21 he was admitted to the Royal National Hospital for Rheumatic Diseases, Bath.

On admission he was a typical case of long-standing rheumatoid arthritis, with an extensive exfoliative dermatitis of seborrhoeic type involving almost the whole body, being particularly severe on the scrotum and in the axillae. There was oozing in the scrotal area, and generalized itching which caused great discomfort. BAL therapy was started on Nov. 10 and discontinued on Nov. 21. A total of 32 ml. was given. On Nov. 18 an area of inflammation (redness, heat, pain, and induration) developed in the right buttock at the site of an injection. This resolved after treatment with local heat and parenteral penicillin. There were no other complications. No amelioration of symptoms occurred until the sixth day after the beginning of treatment, when the itching stopped and it was noticed that the dermatitis was improving.

The patient continued to improve, and on Dec. 8 the rash had almost completely disappeared, only pale pink discoloured areas in various places remaining. He noticed no change in the condition of the arthritis. Corrected suspension stability by the method of Collins *et al.* (1939) was 82% in the first hour at the beginning of treatment and 59% in the first hour on Dec. 8.

Case 2

A miner aged 43 gave a history of typical rheumatoid arthritis dating from January, 1946. He was first admitted to this hospital on Nov. 12, 1946, when he was treated by

rest, physiotherapy, balneotherapy, and myocrisin. Ten injections of myocrisin were given whilst he was an in-patient, and the course was to be completed by his private doctor after discharge. Immediately after the twelfth injection, in February, 1947, he developed a massive generalized exfoliative dermatitis involving almost the whole of his skin surface. The total dosage of myocrisin given by then was 0.86 g. He was readmitted to hospital on June 3, when it was found that there had been a dramatic improvement in his arthritis; he now had no obvious manifestations of the disease, and the corrected suspension stability had improved from 58% in the first hour on the previous admission to 92%. However, a generalized exfoliative dermatitis involved the whole of his body, including scalp and face, associated with severe itching.

He was admitted for the third time on Oct. 21, when his general condition was found to be unchanged. His dermatitis had become more chronic: very little skin surface was not involved, and there were large areas of induration, especially over parts subject to pressure and where he had scratched himself. BAL therapy was started on Oct. 24 and concluded on Nov. 21, a total of 56 ml. having been given. There was no marked improvement until Oct. 30, when the itching ceased completely and the exfoliation was noticed to be less severe. The condition steadily improved, the rash gradually disappearing and the areas of induration becoming softer. On Dec. 1 only pinkish discoloured patches remained, and these were confined to those parts where the dermatitis had been most severe and the induration maximal. There were no complications during the treatment. Corrected suspension stability in the first hour was 83% at the beginning of treatment and 88% on Nov. 28.

Discussion

In these two cases the effect of BAL on gold dermatitis was dramatic. This was particularly so in Case 2, in which the condition was very severe and had existed for nine months before treatment was started. No other case of over three months' standing relieved by BAL can be found in the literature, and in one case of three months' standing the dermatitis proved resistant to BAL (Ragan and Boots, 1947).

The occurrence of inflammation at the site of injection is of interest. Similar complications have been reported (Lockie, Norcross, and George, 1947), but in view of the striking relief of symptoms it is not felt that this is an indication for stopping treatment.

An interesting point emerging from both these cases is the time interval of six days after institution of treatment before improvement began. No such regular period has been noted in other reports.

Frequent blood counts, corrected suspension stability estimations, and urine examinations were done, but no significant change was noticed during the course of treatment. There were no complications except the inflammatory reaction in the buttock already described.

Ragan and Boots (1947) suggest that after relief of dermatitis by BAL, symptoms of rheumatoid arthritis previously improved by aurotherapy might recur within a month. No such change has yet been noted in these two cases. Both have now been under review for four weeks. In Case 1 the fall in corrected suspension stability after treatment was stopped was not considered significant from this point of view, because of the associated inflammatory complication.

Summary

Two cases of dermatitis due to aurotherapy treated by BAL are described, one of a more chronic type than any so far described in the literature.

The type of preparation of BAL and its method of administration are detailed.

The complications are discussed.

The return of symptoms of rheumatoid arthritis after therapy has not been noted in these cases.

The same time interval of six days between institution of treatment and relief of symptoms occurred in both cases.

I should like to express my thanks to Dr. J. B. Bennett for kindly allowing me to treat these cases, and to Dr. G. D. Kersley and Dr. H. J. Gibson for their encouragement and help in preparing this paper.

"AMELLIN" FOR DIABETES

BY

H. WHITTAKER, M.R.C.P.

(From the Diabetic Clinic, King's College Hospital)

"Amellin," an extract of *Scoparia dulcis* (broom), has been claimed by Nath¹ to have an important therapeutic action in diabetes. A critical study of his papers gives no clear evidence of this; indeed, the reasoning is so widely divergent from current views on carbohydrate metabolism as to be an argument against his thesis. However, since amellin appears to have inspired some credence in India it seems desirable to give it a trial.

In two cases this was done, and the results, after careful investigation, show no effect of this substance on diabetes. Some details are here recorded of one case without an another with insulin. Both patients were supplied with a mixture of amellin, calcium gluconate, and lactose, and were instructed to take a measured 5-gr. (0.32-g.) dose by mouth thrice daily for three months.

Case 1.—A factory worker aged 57 was found to have diabetes in May, 1946, but before this trial had received no treatment other than restriction of his daily carbohydrate to 180 g. The blood sugar had gradually fallen from 348 mg. per 100 ml. at the onset to 144 mg. per 100 ml. in November, 1946. Thereafter his diabetes became progressively worse, so that heavy glycosuria and hyperglycaemia (blood sugar, 252 mg. were constant by July 2, 1947. Insulin was obviously necessary at this stage, but was withheld in order to test amellin. After three months of treatment with this drug his weight had fallen by 1½ lb. (680 g.), traces of ketone bodies accompanied his glycosuria, and the blood sugar was 348 mg. per 100 ml. His general health had declined to a state comparable to that at the onset of his disease. When protamine-zinc-insulin, only 16 units daily, replaced amellin, his weight rose by 3½ lb. (1.59 kg.) the urine became sugar-free, and the blood sugar four hours after breakfast was 206 mg. per 100 ml., while his general health showed the usual improvement.

Case 2.—A Civil Servant aged 47, who in the course of a routine medical examination in 1938 was found to have diabetes had since the inception of treatment kept detailed records of his tests and progress. When amellin was begun on June 2, 1947, his urine contained large amounts of sugar by reason of his low renal threshold, but ketones were absent and the blood sugar five hours after his single mixed daily dose of 24 units of protamine-zinc with 12 units of soluble insulin was only 46 mg. per 100 ml. The soluble insulin was reduced by 4 units and amellin started with no alteration in his daily carbohydrate. On Sept. 3, 1947, after three months of amellin, the urine showed traces of ketone bodies with heavy glycosuria, the blood sugar four hours after insulin was 125 mg. per 100 ml., and his weight had fallen by 7 lb. (3.18 kg.). His previous record

showed comparable variations, and it was obvious that amellin had not made the slightest difference to the closely studied pattern of his progress.

This test was undertaken on the suggestion of Dr. R. D. Lawrence and Prof. F. G. Young at the request of the Medical Research Council and the (then) India Office. Acknowledgment is due to Prof. M. C. Nath for his kindness in supplying a sample of amellin for the test.

THE PRE-ERYTHROCYTIC STAGE OF HUMAN MALARIA, *PLASMODIUM* VIVAX

BY

H. E. SHORTT, M.D., D.Sc., D.T.M.&H.

P. C. C. GARNHAM, M.D., D.P.H.

G. COVELL, M.D., D.T.M.&H., D.P.H.

AND

P. G. SHUTE

In the issue of *Nature* dated Jan. 24, 1948, Shortt and Garnham reported the finding of pre-erythrocytic forms of *Plasmodium cynomolgi* in the liver of *Macaca mulatta*. A more detailed description of the appearance of these parasites, as seen on the sixth and seventh days of the incubation period, was given later by Shortt, Garnham, and Malamos (1948). *P. cynomolgi* being so closely similar in its morphology and life-cycle to *P. vivax* of man, it was reasonable to infer that, at a corresponding stage of the incubation period of an infection the pre-erythrocytic stage would also closely resemble that of *P. cynomolgi*.

The affiliation to the London School of Hygiene and Tropical Medicine of the Ministry of Health's Malaria Laboratory at the Horton Hospital for Mental Diseases, Epsom, where malarial treatment of general paralysis is carried out as a routine, supplied the means of verifying this supposition, and suitable arrangements were made through Dr. G. Macdonald, Chairman of the Tropical Course Subcommittee of the Council of the London School of Hygiene and Tropical Medicine. As there was at the time no suitable patient about to undergo this treatment at Horton Hospital, we applied to the Bucks County Mental Hospital, Aylesbury. The superintendent, Dr. J. S. I. Skottowe, who had a patient requiring malarial infection by mosquito-bites, was lad to co-operate with us, and transferred the patient to Horton for treatment, at the same time obtaining his consent and that of his wife to the performance of a biopsy on the liver during the incubation period of the infection.

Infection of the patient was effected by feeding upon him, on two successive days, a large number of *Anopheles maculipennis atroparvus* mosquitoes infected with *P. vivax* and by the intravenous inoculation of isolated salivary glands of a certain number of the same mosquitoes. Seven days after the first feeding by mosquitoes a biopsy was performed on the liver under local analgesia by Mr. E. J. Radley Smith. The material, when examined in sections, revealed the presence of plasmodial masses studded with hromatin particles very similar in appearance to those previously seen in the case of infection of the monkey with *P. cynomolgi*. The forms seen measured up to 42µ

in diameter and showed in some instances the vacuoles noted in the case of *P. cynomolgi*.

There seems no doubt that these bodies are the pre-erythrocytic forms of *P. vivax* in man. The material in our possession is being studied and further observations will be communicated when completed.

In recording this finding we wish to express our indebtedness to Dr. Skottowe for his help in obtaining a suitable patient requiring treatment by mosquito-induced malaria; to Dr. W. D. Nicol, superintendent, Horton Hospital, for admitting this patient and for making all the arrangements for our investigation; and to Mr. E. J. Radley Smith, who performed the biopsy of the liver. The technical operations connected with this investigation were most efficiently carried out by Messrs. W. Cooper and E. Blackie, and Misses Wall, Stedman, and Marjion.

Medical Memoranda

Allergy to Penicillin

The personal experiences outlined in the following case report may be found of interest.

CASE HISTORY

The patient, a general practitioner aged 34, had a personal and family history of migraine, and a family but not personal history of hay-fever. On May 8, 1947, he fractured the neck of the femur. Open reduction was carried out under general anaesthesia on May 12, and reduction in imperfect position was maintained by a Smith-Petersen "pin." Convalescence was interrupted by 20 to 25 stitch abscesses between June 1 and Sep. 1. A keloid scar developed. He had a fixed flexion of 35-40 degrees and a nocturnal pyrexia of 99.8° F. (37.7° C.) throughout. There was a leucocytosis of only 10,650. On Oct. 10 radiographs gave no evidence of bony union, and the condition was unaltered. Comparative radiographs showed possible bone abscess in the great trochanter. The "pin" had not shifted. From Oct. 21 to 25 inclusive he was given 500,000 units of penicillin intramuscularly three times a day (total 7,500,000 units). There was no history of previous penicillin therapy.

The immediate results of penicillin therapy were: pyrexia abolished, fixed flexion reduced to 10 degrees, regression of keloid scar, great diminution of pain, and general condition much improved. There was no change in this encouraging state (except that a radiograph on Nov. 11 showed the first sign of callus) until Nov. 12 (17 days after cessation of penicillin therapy), when he was awakened at 4 a.m. by irritation of the left eyelid. During the day general simple urticaria developed, with lesions up to 4 cm. square. Next day the condition was the same. Very little of the body was unaffected. "Benadryl" in full dosage was given without benefit. The temperature was 99.6° F. (37.55° C.), and the pulse 100. On the 14th the swelling was less of the cutaneous and more of the subcutaneous tissues ("angioneurotic oedema" or Quincke's disease). Adrenaline hydrochloride in doses of 5, 5, 8, 10, 10, and 15 min. (0.3, 0.3, 0.5, 0.6, 0.6, and 0.9 ml.) was given at intervals, with no benefit. The temperature was 99.8° F. (37.7° C.), and the pulse 90-110. Two "antistin" tablets were given thrice daily on the 15th and 16th, with no benefit. Oliguria and dysuria were present.

On the 17th periauricular swelling of various joints (large and small) occurred. Each lesion lasted about 36 hours after a precipitate onset. No benefit was derived from 1/2 oz. (14 ml.) mist. sed. salicyl. two-hourly. The temperature was 99.2° F. (37.3° C.), and the pulse 90. He had epigastric discomfort and diarrhoea. "Anthran" was tried without effect.

In addition intermittent oedema of fauces, glottis, and tongue occurred from Nov. 18 to 21, and from the 19th to the 24th asthma and paroxysmal rhinorrhoea occurred intermittently by day and night. This was relieved by ephedrine 1 gr. (65 mg.) by mouth. He had considerable pain in the hands and feet and severe pruritus all over the body, especially on a change of temperature. His temperature was still 99.2° F. The pulse was steady except during asthma.

In view of dermatographism and the obviously "vascular-permeability" nature of the residual symptoms a course of 20 mg. of vitamin K (synthetic) twice daily was started on Nov. 23. Whether by coincidence or not, the pruritus ceased immediately and there were no further joint lesions.

I would like to thank Sir Arnold Stott and Dr. P. J. W. Melligan for their care and sympathy during the above troubles.

R. A. SHAWYER, B.M., B.Ch.

Reviews

DANCE OF THE GENES

Genetics, Medicine and Man. By H. J. Muller, C. C. Little, and Laurence H. Snyder. (Pp. 158; illustrated \$2.25 or 12s. 6d.) New York: Cornell University Press. London: Geoffrey Cumberlege (Oxford University Press). 1947.

The material of this book originally consisted of six Messenger Lectures on the evolution of civilization delivered at Cornell University in 1945. The Messenger Lectureship was founded to provide an annual course for the special purpose of raising the moral standard of American political, business, and social life. Although it is somewhat difficult, after reading this book, to imagine how the lectures can directly serve such praiseworthy purposes, they nevertheless must have been both enjoyable and instructive. Three geneticists, each outstanding in his own field, delivered them to a general audience, giving an account of the fundamental principles of genetics, parental influence and the growth of individuality, and the special genetics of man.

Prof. H. J. Muller, simple yet meticulously accurate in statement, presents an account of genetic fact and modern theory. It is doubtful whether anyone who is not already acquainted with the subject-matter of a more pedestrian textbook of genetics would be able to appreciate fully the significance of what Prof. Muller has to say, but those who know the elementary principles of the subject will find most attractive his account of the nature of the genetic material, the nature of the genetic effects of mutations, the gene and the origin of life, the dance of the genes, and gene equilibria in populations. Dr. C. C. Little, Director of the Roscoe B. Jackson Memorial Laboratory, Bar Harbor, recently completely destroyed by fire, draws deeply on his experience as a geneticist working on the mouse. He enjoys unique facilities and uses them to bridge the gap between formal genetics and the processes of development, linking genetics with both physiology and psychology. In his second lecture Dr. Little discusses problems of growth, normal and abnormal, and individuality, in so far as genetic factors influence them. Prof. Snyder in his two lectures presents an astonishingly comprehensive account of the special genetics of man, which must be of particular interest to all who practise medicine. There has been no better short statement of the main facts of human genetics than this.

F. A. E. CREW.

CLINICAL CHEMISTRY

Quantitative Clinical Chemistry Interpretations. By John P. Peters, M.D., M.A., and Donald D. Van Slyke, Ph.D., Sc.D. Volume I. Second edition. Part I. (Pp. 1042. 38s. 6d.) London: Baillière, Tindall and Cox. 1946.

The rapid progress of clinical chemistry imposes a Herculean task upon the authors of such a standard work as this. The first edition appeared in 1931, and by 1937 they decided that the production of a second edition was the only alternative to the book becoming obsolete. They have had wholly to rewrite the text, and to subdivide "Interpretations" into two volumes. In this, the first of these two volumes, they consider the overall energy exchanges and the metabolism of the three major food-stuffs—carbohydrates, lipids, and proteins; in the second they will be concerned with plasma proteins, water, and inorganic elements. They have retained the excellent bibliography embodied in the first edition and brought it thoroughly up to date. In each section the authors first discuss the chemistry and physiology of the substance in question, and then the application of this knowledge to clinical medicine. No better work of reference could be desired by the physician interested in the diseases of metabolism, and an excellent index facilitates use. The authors have fully maintained the high standard that they set themselves in the first edition, and one can only regret that this edition, like its predecessor, will also become obsolete and may not again be re-edited by the same authors.

O. L. V. DE WESSELOW.

HEROIC SURGERY

Radical Surgery in Advanced Abdominal Cancer. By Alexander Brunswick, M.D. (Pp. 324; 118 figures. 42s.) U.S.A.: University of Chicago Press. Great Britain and Ireland: Cambridge University Press. 1947.

This book contains the detailed account of the operations performed upon a series of 100 patients suffering from advanced cancer of one or more of the abdominal viscera. After perusing the book everyone will agree that Dr. Brunswick is a bold, skilful, courageous, and optimistic surgeon. As the author says in the foreword, such heroic surgery would not have been possible without modern aids—blood transfusion, skilled anaesthesia (he favours continuous spinal), the maintenance of fluid and nitrogen balance, and chemotherapy. The fourth chapter, in which he discusses these supportive measures, is worth special study. The author does not allow the idea of prognosis to affect his definition of "operable." He defines an operable neoplasm as "one that can be excised regardless of where or how much spread has developed." Here of course we are on debatable ground, for decision to excise depends so much upon the experience, skill, and judgment of the individual surgeon. It is quite likely that many surgeons would have deemed some of these cases inoperable, certainly the one which led to the most extensive operation of all, in which were excised the whole of the stomach, much of the left lobe of the liver, the spleen, the body and tail of the pancreas, the transverse colon, nearly all the omentum, most of the left upper quadrant of the abdominal wall, and some of the retroperitoneal tissues. The author states that the patient (a young man of 28) was quite comfortable for several weeks, but he died two months after operation. The impression made upon the reader's mind is similar to that which he experiences when first he reads of the charge at Balaclava. The results appear to justify this extensive surgery. Though of the 100 patients 34 died as the result of the operation and 17 obtained no palliation, yet 30 were distinctly relieved and 19 survived in good condition for varying periods; 13 were still living (at the time of publication), with an average period of survival of 40 months.

The author frequently mentions the work of other surgeons in the text, but gives no definite references; this detracts from the value of the book to other surgeons. Moreover, we were surprised not to see anywhere a reference to the extensive and dramatic operations performed by Gordon-Taylor and by Grel Turner, who have both done pioneer work of this kind. Most of these operations would be possible only in the hands of a very experienced surgeon, and we would earnestly caution the young surgeon not to attempt the heroic before he has graduated successfully in the hard school of routine major surgery of the abdomen. For the experienced surgeon this book will be a stimulus and an encouragement.

V. ZACHARY COPE.

RECENT GYNAECOLOGY

Progress in Gynecology. Edited by Joe V. Meigs, M.D., and S. H. Sturgis, M.D. (Pp. 552; illustrated. 35s.) London: William Heinemann (Medical Books), Ltd. 1947.

Dr. Joe V. Meigs and Dr. S. H. Sturgis have published this up-to-date account of recent work in gynaecology for the special requirements of those ex-Service doctors who were unable to read the literature during the war. They asked individual American specialists to write chapters on subjects which were their particular interest in the specialty. The contributors represent a "Ministry of All the Talents" in American gynaecology; the high quality of their work is most impressive and the book as a whole is outstanding. Almost without exception each chapter is full of information concisely arranged and clearly expressed.

Schiller's article is particularly noteworthy for depth of thought and his discussion of biological progress and experiment. John Rock writes on "The Causes and Relief of Infertility" with that peculiar, graceful condensed style which is unrivalled in the prose writings on gynaecology, and of which the author tells me he is quite unconscious. Similarly, Edward Davis's chapter on "The Gonadotrophins in Gynaecology" is excellent, as is that by Reifstein on "The Relation of the Adrenal Cortex to Gynaecology." Dr. Meigs himself has

written on enterocele and on Wertheim's operation, the latter article being particularly important because of his observations on the blood supply to the ureter.

One criticism which has been expressed is that the contributors are too restricted to the neighbourhood of Boston and New York. Hamblen's article alone is insufficient to cover the whole subject of functional uterine haemorrhage, and some of his views are by no means generally accepted. Counsellor's article on the treatment of vesico-vaginal and other pelvic fistulas is too short, although it is well concentrated. The elaboration of Taussig's operation, though well described, is perhaps not theoretically sound; nevertheless, Nathanson's description is beautifully written and illustrated. With the possible exception of Neuweiler's *Gynäkologische Diagnostik* this book is perhaps the most important on gynaecology in the last ten years. It can be read with enjoyment, and every paragraph contains some useful information. Marlowe's "infinite riches in a little room" is perhaps an apt description.

WILFRED SHAW.

CHILDREN'S DISEASES

Diseases of Children. Edited by Donald Paterson, M.D., F.R.C.P. and Alan Moncrieff, M.D., F.R.C.P. Volume I. With contributions by 29 contributors. Fourth edition. (Pp. 771; illustrated. 30s.) London: Edward Arnold and Co. 1947.

The fourth edition of Garrod, Batten, and Thursfield's famous textbook is in many respects a new book. Not only has it lost its last link with the original editors, but many of the contributors are newcomers since the last edition was published in 1934. It has changed its format by dichotomy, and owing to the post-war difficulties of reproduction and delivery the second twin is likely to be born many months later than the first. This volume is a handsome child, of which the two parents and twenty-seven godparents can feel that the prospects of survival are excellent. When we come to examine its internal structure, we still find some of the familiar landmarks—for example, the opening chapter on heredity—but the first part ("General Considerations") is rather a hotchpotch. The account of vital statistics, growth and development, and feeding appear here logically enough, but those of treatment of talipes, hare-lip, and undescended testicle seem out of place in such company. There is a useful section on water and electrolyte control summarizing much of Gamble's work, and others on practical procedures, drug therapy, clinical pathology, and anaesthetics.

The second part ("Diseases of Children") is presented in a more orthodox way and is arranged under systems, though the newborn baby, nutrition, metabolism, allergy, and tuberculosis are separately considered. There is some overlapping between the account of tuberculosis and the section on the respiratory system which is perhaps inevitable. Chapter XV has evidently been misnamed, or should have been combined with Chapter XVII. There are the inevitable startling transitions which always occur in a work by several authors. What a world of difference, for instance, lies between the child who arrives at hospital with abdominal pain (medical aspect of) and the one with abdominal pain (surgical aspects of). One wonders where the child would go who simply had abdominal pain (or where, for that matter, the child with an ischio-rectal abscess: possibly having hunted under "Rectum," we should find it described in the second volume). The editors have also allowed themselves considerable latitude over the reproduction of x-ray photographs as positives or negatives. Thus, infantile rickets appears as one, late rickets as the other; and the legend on p. 324 describing a "dense white line" in scurvy (which is reproduced in the illustration as a dense black line) has evidently so confused somebody that Trummerfeld's zone appears to have been touched up with dense white, and a little extra white added beyond the calcified matrix to give full measure. In view of the advances which have been made in endocrinology in recent years the chapter on this subject is rather disappointing, and we note that over half the seventy-one references are more than twenty years old. Apart from these minor criticisms, however, the authors maintain a high standard throughout, and since the production was undertaken at a time of great difficulty it reflects much credit on editors, contributors, and publishers alike.

R. W. B. ELLIS.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

Science News 6. (Pp. 144. 1s. 6d.) London: Penguin Books. 1948.

Some recent advances in science described for the layman

Nutrition and Diet Therapy. By A. E. Pavy, S.R.N., D.N. (Pp. 304. 12s. 6d.) London: Faber and Faber. 1948.

A detailed account for nurses.

Psychoanalytic Psychiatry. By A. A. Brill, M.D., Ph.D. (Pp. 259. 15s.) London: John Lehmann. 1948

A collection of lectures on psycho-analysis

Handbook on Fractures. By D. Eve, Jr., M.D., F.A.C.S. (Pp. 263. 25s.) London: Henry Kimpton. 1947.

A profusely illustrated manual on the treatment of fractures.

Education and Health. By R. Gamlin, M.A., M.B., D.P.H. (Pp. 372. 12s. 6d.) London: James Nisbet. 1947.

A work on health and hygiene intended primarily for school-teachers.

Modern Plastic Surgical Prosthetics. By A. M. Brown, M.A., M.D. (Pp. 293. 35s.) London: William Heinemann. 1947.

A general account of prosthetic devices and their manufacture, with emphasis on those intended for facial reconstruction.

Illustrative Electrocardiography. By J. Burstein, M.D., and N. Bloom, M.D. 3rd ed. (Pp. 369. No price.) New York and London: D. Appleton-Century. 1948

A practical survey of electrocardiography, with many illustrations.

The Biology of Melanomas. Edited by R. W. Miler and M. Gordon. (Pp. 466. 55; members, 54.) New York Academy of Sciences. 1948.

Papers on pigmented neoplasms in man and animals.

The Past Won't Die. By McKnight: Malmor. (Pp. 120. 6s.) London: Hurst and Blackett. 1948.

A crime story.

Gastritis. By R. Schindler, M.D., F.A.C.P. (Pp. 462. 50s.) London: William Heinemann. 1947.

A monograph on the pathology, clinical aspects, and treatment of gastritis.

The U.F.A.W. Handbook on the Care and Management of Laboratory Animals. Edited by A. N. Worden, M.A., B.Sc., M.R.C.V.S., A.R.I.C. (Pp. 368. 31s. 6d.) London: B. T. B. Tindall and Cox. 1947.

Contains also an appendix on statistical analysis.

A Summary of Surgery for Nurses. By S. Taylor, M.A., M.Ch., F.R.C.S. (Pp. 93. 5s.) London: Faber and Faber. 1948.

Alphabetically arranged synopsis of surgery.

Über die Kaliumbestimmung in Biologischer Substanz. By W. K. Rieben. (Pp. 73. Paper 9 francs; stiff covers 12 francs.) Benno Schwabe and Co.

Biochemical estimation of potassium.

Thromboendangitis Obliterans des Gehirns. By F. Livero. (Pp. 248. 24 Swiss francs.) Benno Schwabe. 1947.

A monograph on thrombo-angitis obliterans of the brain.

Hypnotism Today. By L. M. Leaven, B.A., and J. Bordenaux, B.A., M.A. (Pp. 278. 25s.) London: William Heinemann. 1947.

The theory and practice of hypnotism and its use in psychotherapy.

Counseling in Schools of Nursing. By H. P. Gordon et al. (Pp. 279. \$3.00.) New York and London: McGraw-Hill Book Co. 1947.

Discusses the management of student nurses.

Liber Jubilatis J. Rodhain. (Pp. 409. No price.) Brussels: Imprimeur du Roi. 1947.

A collection of papers on tropical medicine.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY MARCH 20 1948

TOWARDS A DECISION

This week's *Journal* goes to press on the eve of the Special Representative Meeting held on Wednesday to consider the Council's recommendation and to receive the results of the plebiscite. Some of the motions and amendments of divisions were published in last week's *Journal* and give some indication of the trend of opinion, especially among general practitioners. The plebiscite has given the representatives an overwhelming vote of confidence in the policy at present followed. Some 40,000 doctors have expressed disapproval of the Act in its present form, and it is obvious that unless some changes are made very large numbers of doctors will refuse to enter the Service on July 5, and that in any case a service will be begun which can give no satisfaction to anyone, least of all to the public. Mr. Aneurin Bevan in the debate in the House of Commons a month ago said that he desired the enthusiastic and harmonious co-operation of the medical profession in the Service of which he is part architect. After he had made this statement an overwhelming majority of all sections of the medical profession told him that they disapproved of his Act, but since the publication of the plebiscite results he has made no move to inquire into the causes of this disapproval and no attempt to secure the co-operation he considers desirable. The Government has, in fact, said that the Service will start on July 5 whether the medical profession wants to work in it or not. If the opposition to the Act had come from one section only of the profession and had been based on some selfish concern about remuneration, this attitude on the part of the Government could have been understood. In view of the policy of the Labour Party in favour of a whole-time State service, opposition from general practitioners and consultants might have been foreseen. But the vote of no confidence in the Government's Act on the part of those who have freely chosen whole-time service surely must indicate to the Government and the public that the National Health Service Act in part or in whole is an unsatisfactory instrument for providing a medical service for the nation. It is therefore idle for anyone to suppose that the medical profession will agree to work in the new Service under the Act in its present form.

We do not, of course, know what resolutions may have been passed by the Representative Body by the time this issue of the *Journal* is published. But we may note that the recommendation of the Council put before it was couched in moderate and unprovocative terms. Propagandists will no doubt make the usual stupid remarks about

this being an indication of weakness, without reflecting that to be reasonable at the moment of strength is a sign of wisdom. The medical profession is now in the position of having to decide what its ultimate object is. There would seem to be two courses open to it. The plebiscite result can be interpreted as a root-and-branch opposition to the Act as a whole. This is undoubtedly the attitude of some of those who have voted. If this were, in fact, the attitude of the majority of those who expressed disapproval, then the ultimate object would be the removal of the Act from the Statute Book. If the great majority of consultants and general practitioners refused to enter the Service the Act would die a natural death, and a different one would have to be put in its place. Some consider that even if it were amended in certain respects the main effect of the Act—namely, the nationalization of the medical profession—would be unaltered. Many thoughtful medical men see this as part and parcel of the principal political theme of the contemporary world—the relation between the State and the individual. Mr. Butler said in the House of Commons that “you cannot nationalize conscience”; still less can one nationalize the intimate relationship existing between the sick person and his physician. Even if the Act were amended the Minister of Health, a political figure will still have enormous power and what amounts to an autocratic control over the medical profession.

The alternative object would be to reopen negotiations with a view to obtaining satisfactory safeguards against the introduction of a full-salaried State medical service. The British Medical Association, in declaring opposition to the Act in its present form, has implied that if the present Act were altered by amendment service under it could be made possible. The Negotiating Committee, of which the B.M.A. formed half the membership, presented a statement to the Minister last December which he considered raised objections to all the principal provisions of the Act. From the standpoint of general practice, criticism has been directed principally at certain features of the Act and certain proposals of the Minister. Mr. Bevan in December made some minor concessions to consultants and specialists, but in spite of this they expressed their disapproval of the Act by an overwhelming majority. It may well be, therefore, that the consultants, who include the teachers of Medicine, are less concerned with the details that interest the general practitioners, and more concerned with the effect of the Act upon the free development of Medicine under the monopoly control of the State.

The Representative Body may have stressed those matters of special interest to general practitioners, who constitute the majority of doctors. But if negotiations are reopened they must include matters that affect all branches of the profession as well as those that concern the general practitioner. There is no need to enumerate them here or engage in the pointless task of trying to arrange them in order of priority. Of overriding importance is the preservation of the professional and individual freedom of the practising doctor. Should it be possible to reopen discussions with the Government, the central fact of independence must be kept in the forefront and not obscured by a preoccupation

with this or that detail. In negotiation there is always "give" as well as "take." To secure concessions concessions must be made. But no concession could be made that would open the door to the introduction of a whole-time salaried State medical service. We believe Mr. Bevan when he says that it is not his intention to introduce such a service, and it is no reflection upon him to say that this expressed intention is no safeguard to the medical profession, because it would not be binding on his successor in the new Government that will be formed after a General Election to be held within two years from now. There is nothing in the present Act which offers the safeguard required, and the logical conclusion is that nothing short of an amending Act would provide this safeguard.

At the moment of writing the decisions of the Representative Body are not known. They may be related principally to the position of the general practitioner. The British Medical Association, however, has among its members all sections of the medical profession. In proportion, in fact, the consultants and specialists are as well represented in membership as are the general practitioners. The B.M.A. is therefore representative of the profession and is conscious of its obligation to the profession as a whole. It will therefore be essential to take into account the attitude and opinion of the consultant world if these find corporate expression through its organizations. Since the publication in January last year of the letter by the three presidents the Colleges have refrained from any positive expression of opinion except in so far as they contributed to the work of the Negotiating Committee. They cannot, however, long remain silent, and it is much to be hoped that the Colleges will discover what are the views of their fellows and take steps to make them public, hampered though they may be by a machinery that does not include what the Webbs have described as "the devices of advanced democracy."

It is becoming the fashion to compare medical men with miners and other manual workers. Those who do this do not pursue the argument by stating that the miners wanted nationalization in order to pursue their necessary and honourable task with a contented mind. Medical men have asked not to be nationalized because they feel that if they are they will not be able to work with a contented mind. But while the miners are granted their wish, the medical men are denied theirs. This method of consent by compulsion is misnamed "Democracy." Both the Government and the medical profession wish to see that the public has an efficient medical service. The Government claims that their Act will provide this, but we repeat once more that if this Act, even amended, comes into operation on July 5 the public will be disillusioned, and will have a less efficient medical service than at present, for the reason that it will be impossible by July 5—or even for years to come—to provide the necessary number of hospitals, doctors, nurses, dentists, and other health workers. Not to mention health centres. We suggest that it is still not too late for the Government to review this position so that both the public and the medical profession may co-operate in their fight against disease and in the maintenance and promotion of health.

THE WORLD FOOD POSITION

Sir John Boyd Orr, director of the Food and Agriculture Organization of United Nations, told the third conference of that body when it assembled last autumn that the position was no better than it had been the year before, and that unless the war-devastated countries were provided with machinery and fertilizers for the harvest of 1948 the severe food shortage would last for at least two years more. He said also that, taking into account the probable increase in world population, food production would need to be doubled during the next 25 years to provide everybody with a diet capable of maintaining health and working efficiency. Meanwhile the continuing shortage calls for the fullest use of all available sources of food supply, prevention of avoidable waste, protection of vulnerable groups, and careful watch on the nutritional position in general.

If this is a world crisis at least world opinion and resolution are mobilized to meet it. After the first World War the League of Nations measured itself against the prevailing need but took little cognizance of food problems. The word "nutrition" or "food" does not appear in its covenant. It set up organizations to deal with health, with the drug traffic, with social questions, with the resettlement of refugees, but not specifically with famine, though later in its history there was formed the Technical Commission on Nutrition, which has done valuable work, to be continued, it is hoped, under F.A.O. But the United Nations had scarcely been established before F.A.O. became one of its instruments. It was conceived at Hot Springs in 1943, held its first conference at Quebec in 1945, its second at Copenhagen in 1946, its third at Geneva in 1947, attended by representatives of fifty nations. Under its encouragement 34 countries—this was the number last year and is probably now exceeded—have set up national committees. Regional offices have been established or are projected for Europe, the Middle East, Asia, and Latin America. Two regional conferences are planned, in Latin America and in the Far East. The staff of the Organization in Washington, numbering something like 400, is organized in about six divisions—agriculture; economics, marketing, and statistics; fisheries; forestry; nutrition; and technical and administrative services. There is also the nucleus of a division of rural welfare. The work is assisted by six standing advisory committees. The report of the meeting of the Advisory Committee on Nutrition, held at Geneva last September under the chairmanship of Lord Horder, is summarized elsewhere in this issue. The Director of the Organization has sent a cable to Lord Horder approving a suggestion that material in the possession of the Advisory Committee should be made available to the Nutrition Committee set up not long ago by the British Medical Association. Thus a useful liaison between the Association and F.A.O. will be established.

The subject of nutrition and food requirement is extraordinarily well documented. At every meeting the results of new studies become available, and instructions are given for yet more. When the Advisory Committee assembled at Geneva it had to absorb about twenty reports and memoranda. The ordinary man may feel some impatience at so much preliminary surveying when the important

thing is to get more cereals and roots under cultivation and develop animal husbandry, but the object of these reports and the expert consideration they receive is to avoid the wastage and misuse of food which with marginal resources can be ill-afforded. The recent F.A.O. conference was reminded that the very increase of agricultural production achieved by exporting countries in their efforts to relieve the world shortage may well lead to unmarketable surpluses. An observer back from Greece has told how some of the food sent by U.N.R.R.A. wilted in Athens shops, the Greek preferring his traditional bread and olives. The feeding of the world is, after all, a task for experts. If the world managed to survive in an earlier period without the expert it was only because of seeming abundance, and even then there were regional famines and ill-balanced diets for large populations. Indeed, the conclusion of the World Food Survey by F.A.O. was that before the recent World War half the population of the world was underfed in that it subsisted on a diet inadequate to maintain normal health, to allow for normal growth in children, and to furnish energy for normal work.

One of the present tasks of F.A.O. is to collate all research projects in the field of nutrition in various countries, to construct an index of nutrition workers and institutions, and to disseminate information wherever it is wanted. A useful achievement is the co-operation between F.A.O. and the World Health Organization, almost the youngest of the nine or ten specialized agencies of United Nations, and now, twenty-five countries having ratified its constitution, to be established on a permanent basis. The first co-operative effort of the two organizations is a report on child nutrition, intended for the guidance of the International Emergency Children's Fund for the rehabilitation of children and adolescents in the war-devastated countries. This fund is making plans to provide supplementary food, especially dried skimmed milk, for millions of such children. A point emphasized at the recent conference was the need for increasing the amount of dried skimmed milk available, and at the same time there was a Belgian proposal, referred to the divisions, that a study be made of the distribution of fresh milk in different countries. With the improvement of herds in pastoral regions and an increase in mixed farming, a more abundant milk yield may go far to help matters.

At a recent meeting in Rome experts on nutrition problems in Europe considered ways of improving the production and consumption of fruits and vegetables. The Nutrition Division is concerning itself with aspects of cereal technology, cereals in most countries contributing half the calories in the diet. Another special activity of F.A.O. is the collection of data on school meals, on which a preliminary report was made to the conference. School feeding is regarded as one of the most effective ways of ensuring improved nutrition.

Food is a world problem, but, as the report of the third conference states, "problems of nutrition differ in various parts of the world, and it is necessary to attack them on a regional basis." It is here that a world organization proves itself of greatest service. It is able to review national or regional problems relating to food and agriculture in such

a way that the activities and programmes in one region or country can be correlated with those in others. The lessons learned in one part of the world can be applied elsewhere. The experience of one country can supplement that of its neighbour and make good its deficiencies, and accepted principles of a general character can be modified to meet a local situation, having due regard to dietary habits and nutritional state. That is what, through many channels, the F.A.O. is doing.

TYRANNY IN THE UNIVERSITY

Those of us who were at school in the halcyon days before 1914 when we learnt of the murder of Socrates, of the trials by the Inquisition, or of the horrors of the slave trade were easily led to think that such things could never happen again. We thought that with material progress there must also be spiritual progress. But the spirit of tyranny is just as active to-day as ever it was, and the centralization of power in one country after another makes its task easier than ever before. The technique of tyranny is now familiar—infiltration, the political coup from either the right or left by a determined minority not afraid to use force, the purge of newspapers and the radio, the closing of frontiers, the banning of foreign literature, and finally the control of universities and teaching.

In Europe this has now become such a matter of course as scarcely to excite a nine days' wonder. It is perhaps less well known that the same thing has been happening in the New World. When we announced¹ the election as a foreign member of the Royal Society of Prof. Bernardo A. Houssay, the distinguished physiologist and Nobel Prize Winner for 1947, we referred to the fact of his dismissal from the University of Buenos Aires. Since then things have gone from bad to worse, and now there are no fewer than 1,073 members of the staffs of the six Argentine Universities who have been either summarily dismissed or compulsorily retired, or have voluntarily resigned. A pamphlet has recently been issued by the Federation of Societies for Defence and Advancement of the Democratic and Free University of Argentina entitled "The Enslavement of the Argentine University." The preface of this pamphlet outlines very clearly the present situation in the country:

"During the current political crisis, for our country the major one in fifty years, the university professors of Argentina, responding honourably to the democratic tradition and to the demands of citizenship, have opposed themselves firmly to the advances of a dictatorship which arose from the militarist movement of 1943. In doing so, they complied with their civic duties, inescapably imposed upon them by their position as teachers of the youth. It was not only the professors who raised their voice against the dictatorship. The students of all the Argentine universities responded similarly in the defence of the basic institutions of the country, gravely endangered at this sad hour of our political evolution.

"The Decree of Intervention, pronounced in May, 1946, was an act of vengeance against this patriotic attitude; its aim was to dismiss from their posts all who, maintaining their duties as teachers, also complied with their civic duties. The Government dismissed all the Rectors, the great majority of the Deans, and a large number of Professors, whose lives had been dedicated to teaching and to scientific research. No consideration was given to, nor respect shown for, the prestige which the work of these savants had brought to Argentine science.

"Through the vindictiveness of the Government, the students of Argentina have received the most impressive lesson of their careers; but happily for the future of the country, they have

¹ *British Medical Journal*, 1947, 2, 698.

protected and cherished their high ideals without equivocation. In all manner of means they have expressed their respect and regard for their dismissed professors, who had undertaken their civic and patriotic activities only because of high moral concepts and at risk to their personal interests. Many students have been imprisoned, suspended, or dismissed; some have had to continue their studies out of the country, finding it impossible to do so in the halls of the Argentine universities.

"Time cannot erase the humiliation which has been heaped, not on the professors themselves, but really on the dignity of the university professions. Despite the formal return to constitutional law, the universities have undergone actually no change either with respect to acts of the Government or the decisions of professors and students. The Government maintains the Argentine universities in the same state of vassalage; students and professors continue their protest against the situation.

"Through the imposition of the new laws, the Free University will disappear, and with it justice and right for the professors, freedom to teach, and stimulus to investigators who will never feel secure in their classrooms and laboratories. With the dismissal of the group of professors who gave lustre to the nation's universities and examples to the youth, and with authority, through the new laws in other hands, the universities will have ceased to be fountains of learning and will have become mere technical schools and mouthpieces for the bureaucracy of the Government."

We believe that this sort of thing "can't happen here." Nevertheless there are danger signs. The publication of any scientific periodical can easily be impeded, delayed, or even suspended by failure to allot the necessary paper. The import of scientific books or periodicals from abroad is already controlled and curtailed. Men of science are having a hard fight to maintain their integrity against the demands for secrecy of Government Departments, and in research institutes there is the tendency for commercial interests to muzzle and hamper the spirit of unfettered scientific curiosity. Since our universities are now largely financed by Government grants there is temptation for the Government to exercise control—no doubt in the public interest. But who is to interpret public interest—the omniscient "omni-incompetent" State, or those who in the universities preserve the values of our civilization?

FRESH THOUGHTS ON HARRISON'S GROOVES

Publications of purely clinical findings are all too few, and there appears elsewhere in this issue a paper by two young physicians—Dr. J. Naish and Dr. H. R. E. Wallis—regarding the significance of Harrison's grooves, which is in every way a happy choice of subject. These authors point out for the first time that this physical sign was the observation of one Edwin Harrison and not of the better publicized Edward Harrison, and that the former indeed wrote very little. Having cleared up this obscurity they then turn to the question of the actual mechanism of the formation of the grooves. Much confusion regarding this point exists even to the present day, and they are certainly not produced at the attachment of the diaphragm to the ribs, as many textbooks continue to assert. The suggestion now put forward is that these transverse depressions occur in a zone between the upper ribs, which move upwards, forwards, and rotate outwards, and the lower ribs, which move outwards and backwards—thus increasing the transverse diameter of the upper abdomen. In the presence of increased negative pressure in the thorax the point most likely to buckle would be at that zone where the two movements diverge, a point that has been termed the "muscle gap."

A study of various groups of children in Bristol led Naish and Wallis to conclude that as many as 45% of

normal school-children have detectable grooves, and about 7% have grooves as deep as 3/16 in. There is no reason to think that the grooves are particularly common in mild rickets, though they are frequent in severe forms of the disease, and the contention that Harrison's sulcus is valueless as a sign of early rickets is again confirmed.

The connexion between bronchitis, whooping-cough, measles, or any severe upper respiratory infection in early life and the development of these sulci could not be proved on statistical grounds, although the deformity was more common in children who had suffered from these diseases. In asthma, on the other hand, the incidence was heavy, and long-standing asthma was the commonest aetiological factor.

A curious finding was the frequency in which the condition was associated with congenital heart disease, but no firm explanation is offered. Indeed the exact mechanism of the development of these grooves remains in some doubt, though the presumption is that it is associated with conditions producing increased intrathoracic traction. Be that as it may, this paper is a very useful contribution to the lore of clinical signs.

TESTOSTERONE IN ANGINA OF EFFORT

John Hunter observed that Nature resorts to vascularity when she has work to do. Prodigious in most things, Nature needs encouragement, and the patient needs help with exogenous coronary vasodilators in cardiac effort pain: for there seems little doubt that the relief from pain given by nitroglycerin and other related drugs is due to augmented coronary blood flow. Although it is now generally agreed that the symptom of cardiac effort pain, or angina of effort, originates in myocardial ischaemia, the many remedies which have been suggested should remind us that the unsolved problems include the influence of temperament, emotion, and suggestion, the absence of correlation between the severity of the pain and the extent of ischaemic myocardium, the impracticability of finding out what would happen in any individual case if we did nothing, and the difficulty of assessing the action of a drug in a disease where all other symptoms are dwarfed by the purely subjective symptom of pain.

Prolonged treatment of angina of effort with testosterone propionate has been increasingly advocated in the last few years. Waldman¹ has reviewed the results of this treatment in 74 cases in the literature. He has added ten cases of his own in which, unlike many of the other cases, there was adequate regard for control periods and in which full use was made of those electrocardiographic criteria which are reasonably supposed to indicate myocardial anoxia. His conclusions were that testosterone propionate in no way replaces the well-established coronary vasodilators such as nitroglycerin in the treatment of acute attacks but that when it is given in 25-mg. doses intramuscularly twice weekly for a minimum period of eight weeks it usually produces a sustained improvement. Side effect could be regarded as insignificant. Lesser² more recently reported a series of 109 cases which he treated with testosterone propionate, some of his earlier cases having been included in Waldman's review. His conclusions appear to rely less on controls or objective criteria than on the size of his series. The dosage and period of treatment are much the same as those given by Waldman, but both authors stress that "individualization" is necessary and some patients need treatment for five or six months before prolonged improvement occurs. In Lesser's series of 109 cases 9

¹ *J. clin. Endocrinol.*, 1945, 5, 385.

² *Ibid.*, 1946, 6, 549.

improved—51 of these to such an extent that each "was able to increase his physical activity without precipitating an anginal attack for a period of at least two months after testosterone therapy was discontinued." As Lesser points out, it would be most unusual for the almost uniform improvement to occur spontaneously in such a large series, and he attributes these good results to testosterone propionate, adding a warning against intensive therapy, to which he attributes acute cardiac failure in one of his patients who was given 25 mg. of testosterone propionate daily for one week.

There are several concepts of the mechanism of testosterone therapy in angina of effort, summarized by Waldman. All of them seem very speculative, and they are perhaps best passed over with the thought that many respectable drugs of accepted therapeutic value have had even stranger origins. More extended and carefully controlled trials are necessary before the long-term treatment of angina of effort with testosterone can be established.

THIRTY-MILLION VOLT X RAYS

Further details can now be given of the 30-million electron volt synchrotrons which are being built for the Medical Research Council and the Atomic Energy Research Establishment of the Ministry of Supply. In so far as their medical use is concerned the generation of x rays of such voltage will substantially increase the ratio of depth to surface dosage, compared with either existing x-ray equipment or radium bomb irradiation.^{1,2} The synchrotron is merely one possible method of accelerating x rays to the required high voltage, and the x rays are generated, as with ordinary equipment, when the electrons thus accelerated hit a metal target. The particular combination of magnetic and electrical acceleration which the synchrotron achieves was first demonstrated, as an experimental system, by the Telecommunication Research Establishment at Malvern, and subsequent development up to the manufacturing stage has been in the nuclear physics laboratories of the General Electric Company at Stafford, where a demonstration of progress to date was given recently.

The first of the synchrotrons, destined for the Atomic Energy Research Establishment, is now physically complete and at an advanced stage of testing; the second and third to be produced will go to the Medical Research Council. In external form they are cylinders about four feet in diameter, and their weight is about three and a half tons. Whilst a formidable piece of equipment, the synchrotron is reasonably compact considering the high energies produced. The x-ray beam emerges from a fixed point (the target) and, with reference to the synchrotron, its direction remains constant. The beam is about 15 degrees in total width—and the word "total" should perhaps be emphasized, since beam-widths are often measured to half intensity. For medical use, provision will be made for the rotation of the complete synchrotron about its axis, and with gimbal-mounting direction of the x-ray beam will be a simple matter. The synchrotron, thus given effective mobility in three dimensions, will be set up in the treatment room so that patients will lie beneath it, in general at about a metre from the point of emergence of the beam. Control will necessarily be remote, since workers in the department must obviously not be continually exposed to stray radiation. A small television apparatus has accordingly been designed which will enable those responsible to observe continuously from the control room the condition and position of the patient. Thus, if the patient had moved so

that the beam was no longer being correctly directed treatment could at once be suspended.

A further piece of equipment, which was also shown, is of experimental rather than therapeutic interest. This is a pulse-operated generator, designed to provide extremely high doses of x rays for short periods. With individual pulses of irradiation of only about half-a-millionth of a second duration—a similar length of time to that used in some forms of radar equipment—a dosage equivalent to 2,500,000 r per minute can be attained—roughly fifty times greater than the highest rate about which published information is available. For comparison, the accepted safety limit in atomic energy plants is 0.1 r in a full eight-hours working day, and, below this again, radiation-recording equipment is available which will give a full-scale reading at one-tenth of the permitted rate; finally, at one-tenth of the latter, and at one-hundredth of the permitted level for atomic energy workers, we reach the inevitable permanent background of irradiation provided by cosmic rays. The total range in rate of dosage between cosmic radiation and the experimental pulse generator already mentioned is accordingly of the order 10^{12} to 1—a figure which is perhaps more eloquent than a verbal description of the engineering progress which has been made.

Further developments in this field include a 300-million electron volt synchrotron planned for the department of physics at Glasgow University. A similar machine is under construction at the Massachusetts Institute of Technology. Prof. Kerst, of the University of Illinois, Urbana, also plans to accelerate electrons to 300-million volts with the older betatron type of equipment which he himself developed. Although 300-million volt x rays are thus already within sight, it appears unlikely that for therapeutic purposes there will be any advantages in going much, if at all, beyond the 30-million volt generators now available.

INTERNATIONAL CONGRESS OF INDUSTRIAL MEDICINE

The 9th International Congress of Industrial Medicine will be held in London from September 13–17 of this year under the patronage of the King and the Queen. The last Congress was held ten years ago, and the first in 1906. The success of past Congresses has been in no small measure due to the inspiration of Prof. Carozzi, who is taking an active part in securing the success of the Congress to be held this year. As is befitting in an industrial country, the Government is officially sponsoring the Congress, and the following Ministers have agreed to serve as Vice-patrons: Mr. Ernest Bevin, Mr. G. A. Isaacs, Mr. Aneurin Bevan, Mr. James Griffiths, Mr. G. R. Strauss, and Mr. H. T. N. Gaitskell. Lord Moran and Sir Alfred Webb-Johnson have accepted office as Presidents of the Congress; Mr. T. E. A. Stowell is Chairman of the British Committee and Dr. Donald Hunter of the Planning Committee. The programme of papers is not yet complete, but it has been decided that various sections will deal with such subjects as: Young Persons in Industry; the Determination of Dusts in Air; Administration and Training; Pneumoconiosis; Dermatology; Burns; Industrial Medicine in the Tropics; and the Training of Industrial Medical Officers. There will be a discussion on rehabilitation, and arrangements have been made to visit various rehabilitation centres, clinics, and hospitals. The official languages of the Congress are French and English, and those who wish to have further information should communicate with the Organizing Secretary, Room 501, Garden Court Wing, B.M.A. House, Tavistock Square, London, W.C.1.

THE FOOD CRISIS AND THE F.A.O.

RECOMMENDATIONS OF ADVISORY COMMITTEE ON NUTRITION

The Food and Agriculture Organization of United Nations has standing advisory committee on nutrition, which held its first meeting at Copenhagen in 1946 and its second at Geneva in September of last year. The second meeting, which took place under the chairmanship of Lord Horder, was attended by thirteen members from eleven countries and three observers and lasted for nine days.

One matter to which the Committee drew attention was the agenda of the regional conferences which F.A.O. is arranging. It was considered that these conferences should centre on three main subjects: (1) the most important problems of nutrition in the region concerned, with special regard to areas within the region in which malnutrition is particularly serious; (2) practical measures for improving nutrition; and (3) a follow-up by means of national organizations. One of the practical measures recommended is to devise programmes for certain demonstration areas "calling for the co-operation of experts in nutrition, agriculture, animal husbandry, fisheries, sociology, cultural anthropology, and home management. These demonstration areas would serve as training grounds for field nutrition workers."

On the question of school feeding, on which a large amount of information has been collected, the Committee felt that the Nutrition Division of F.A.O. might do more than present a picture of the situation in different countries; it should attempt to provide guidance for those concerned in the organization of school feeding. School meals should, wherever possible, be rich in protective foods, and should effectively supplement home meals. "Definite merit attaches to the 'mid-morning snack' which is in vogue in some countries."

Another recommendation was that the Division should prepare and periodically revise tables of food composition for international use, should encourage research on composition of foods, methods of analysis, and correct identification, description, and classification of foods, and should support the study of chemical composition and physiological value of foods which have been insufficiently investigated, and of products newly recognized as food.

A series of recommendations were also made concerning food technology: that there should be a study of the comparative nutritional value of different types of rice produced in different parts of the world; that dried skimmed milk should receive attention; that more use might be made of soya bean products in the emergency; that dried yeast had nutritive value as a supplementary food for human beings; and that more information should be obtained on the subject of synthetic digestible fats and their nutritive value.

Education in Nutrition

The Committee reinforced the view which it expressed at its previous meeting in 1946, that education in nutrition is of prime importance, that it should begin with the child, that school feeding is itself a valuable means of nutrition-teaching; also that "the family doctor, being in a key position, should be taught the principles of nutrition in his preclinical studies, and should be familiar throughout the whole of his clinical training with the many ways in which degrees of malnutrition enter into disease processes." The report adds: "The crux of the position, admittedly unsatisfactory, seems to lie in the question, Who shall teach the teacher? The answer, in great measure, lies with the universities."

Other subjects on which the Committee made recommendations included the preparation of memoranda on the technique and interpretation of diet surveys, physiological requirements for calories and nutrients, and the assessment of nutritional status. The Committee reaffirmed its view that lessons of value for the future can be drawn from the study of nutrition and food management during the war and its aftermath, and recommended that the Nutrition Division should keep itself informed about relevant studies in this field which have been made in different countries.

In the course of its sitting the Committee received a deputation from the League of Red Cross Societies, which pointed out that it represented a very large body of voluntary workers

experienced in the handling of school meals and in education in nutrition, and the Committee drew the attention of the Director-General to this fact and expressed the hope that ways and means of collaboration between the F.A.O. and the League might be found.

Of the many documents before the Committee one of the most valuable was a text prepared by one of its members, Dr. Isabella Leitch, of the Rowett Institute, Scotland, entitled "Preliminary Notes on Vital Statistics and Standards of Living," in which the relations between mortality, occupation, social and economic status, and nutrition were discussed. This analysis is to be developed further on the nutritional side, and is likely to clarify an issue of great interest and importance to F.A.O.

WORLD FOOD SITUATION

Prof. J. R. Marrack, who holds the chair of chemical pathology at the London Hospital Medical College, addressed the Anglo-Austrian Society in the theatre of the British Council on March 11 on the organization of world food supplies. Mr. A. L. Bacharach presided.

During the recent war, said Prof. Marrack, the United States managed to produce more food than ever before for its own people and for export, and it was realized that here was an example of what might be done, through a proper system of production and regulation, towards eliminating malnutrition throughout the world. At the Hot Springs Conference in 1945 the problem was seen to be not the production of the food but the ability of the consumer to pay for it. Even though farmers set themselves to produce as much food as possible, if the power of buying was restricted the depression of the early 'thirties would be repeated.

It was unfortunate that the scheme envisaged at the Hot Springs Conference was not put into force at the end of the war. U.N.R.R.A. was formed not only for the administration of relief but to rebuild the economies of the occupied countries of Europe, but unfortunately, in the final draft scheme for U.N.R.R.A., although the second purpose remained in its name, rehabilitation was in fact dropped and the scheme became one merely of emergency relief. U.N.R.R.A. had supplied food only to those countries which could not afford to pay for it, and the countries which could afford to pay had started a scramble for inadequate supplies. Thus the whole idea of supplying each country according to need fell to the ground.

Disappointed Hopes

Out of the Hot Springs Conference arose the Food and Agriculture Organization of United Nations. Prof. Marrack held that this Organization should have been enabled to buy and hold stocks of food, to supply countries in need, and to administer finance in such a way as to give farmers throughout the world the necessary farming equipment. Sir John Boyd Orr had contemplated the building up of buffer stocks of food so that when there was abundance the Organization could buy and supply to areas where food was scarce. But what had emerged in the end, instead of an international body to buy stocks, was an agreement that individual countries should buy. Prices had been fixed for wheat—the key commodity—and an agreement had been made whereby three out of the four great producing countries would during the next five years produce at amounts which a large number of consumers would take. This gave security to farmers, but it did not give international control of food production, nor did it include arrangements for holding back buffer stocks for relief and improvement of nutrition all over the world. The scheme was essentially a restrictive one, whereas Orr's original scheme was one of expanding economy, ensuring freedom from unemployment by stimulating food production and making sure that malnutrition should cease.

Prof. Marrack contrasted effectively the relative lack of achievement in the application of science to agriculture and the achievements in recent years in medicine. If in agriculture and agricultural economy the same scientific methods had been pursued with the same conviction and enthusiasm, in the prevention of diseases of animals and plants, in the planning of production and regulation of distribution, the spectre of malnutrition might no longer haunt the world. He concluded by saying that the western nations of Europe could not unite for a better purpose than to run a food organization.

GUY'S HOSPITAL DENTAL SCHOOL

The annual clinical meeting of Guy's Hospital Dental School took place on March 6, when the departments and theatres were crowded with old students for a full programme of demonstrations and exhibits. The emphasis in the exhibition was on preventive dentistry. The x-ray department showed the advantages of intraoral stereoscopic projections. The prosthetic laboratory contained some interesting models in acrylic resin, and this material found various uses in the conservation-room. Among the pathological and experimental specimens in the research laboratory were the results of an investigation on the effect of prematurity on tooth enamel. Radiographs and photographs indicated that where there had been no illness in pregnancy the position of the infant's teeth was well marked, the neonatal line corresponding to the degree of prematurity; but where there had been severe constitutional disturbances there was evidence of interrupted enamel deposition and altered structure. In the conservation-room some work on the use of penicillin in root canal therapy was demonstrated. Various methods for the prevention of dental caries were illustrated: the application of sodium fluoride in distilled water; the use of zinc chloride and potassium ferrocyanide; and a mouth-wash and dentifrice based on the effect of ammonia nitrogen on the growth of the lacto-bacillus acidophilus. It was stated that the regular use of this mouthwash and tooth-powder had been shown to produce a marked reduction in the oral lacto-bacillus counts, but confirmatory evidence of a reduction in actual caries was still awaited.

The preclinical department showed the methods of stress analysis which had been adapted for the study of stress distribution in the different parts of a clasp with the object of reducing high stresses and consequent danger of breakage. The making of copper dies of the teeth as a means of ensuring accuracy and hardness for fillings, crowns, and bridges was also shown. Besides the various demonstrations, operations for osteoma of the jaw, for ankylosis of the temporomandibular joint, and for other conditions were undertaken.

Nova et Vetera

CENTURY OF CERTIFICATION

That the provision of certificates worried medical practitioners 100 years ago is shown by the following letter that appeared in the "Provincial Medical and Surgical Journal," the predecessor of the "B.M.J.," on March 22, 1848.

Baptism of Sick Infants

SIR,—May I beg the favour through the medium of the *Provincial Journal*, of inquiring of my professional brethren, how they are in the habit of treating certain applications made to them under the following circumstances?

It appears that the clergy in the diocese of Norwich, and, most probable, the same is the case elsewhere, are instructed that the baptism of infants shall only be performed in strict conformity with the rubric, and that the practice of a preliminary baptism or "naming," as heretofore customary, should be discontinued. In complying with this ordinance, the clergy, as if by a mutual understanding, have set apart one Sunday in each month, and it is expected all children born in the intervening period, shall on this day be brought to the font, attended by the required sponsors. Now, it happens not unfrequently, that an infant is attacked with sickness previous to the advent of this important day, and the parents, anxious to secure it a christian burial, and perhaps, if imbued with faith in the doctrine of baptismal regeneration, dreading the death of their infant unregenerate, apply to the minister to have it baptized. The answer is—"Unless you bring a certificate from a surgeon, stating that the child's life is in imminent peril, the rite cannot be performed." Hitherto I have declined giving the necessary document, as I can only regard such a demand on the part of the clergy as tending to fasten unduly a solemn responsibility on the medical profession, which naturally belongs to themselves.

I am, Sir,

Your most obedient servant,

JAMES COOPER.

Filby, Great Yarmouth, Norfolk.
March 3, 1848.

Preparations and Appliances

A DEMONSTRATION WALKING CALLIPER-BOOT

Mr. HORACE DAVIES, visiting orthopaedic surgeon, Birkenhead Municipal Hospital and Whiston County Hospital, writes: It is often difficult to demonstrate in a convincing way to students and nurses the principle of the weight-bearing walking calliper. We have to rely mainly upon the patient's word that his heel is not in contact with the boot. This is particularly difficult in children, especially if the calliper has to be worn for a lengthy period, and constant adjustments are necessary. The heel-boot space can, of course, be shown by removing the back of the boot, but this is of use only in a demonstrative model. A serviceable method enabling normal use of the calliper is shown in the accompanying photograph. An oblique

piece of the boot is removed from the inner side and replaced by "perspex." The plastic is inserted from the top, between the leather and the lining, and then cemented into position using a waterproof plastic glue. Through this window the heel and the space below can easily be seen and adjustments of calliper length made with precision.

ROUGHENED NEEDLE-HEAD FOR TREATMENT OF VARICOSE VEINS

Mr. R. ROWDEN FOOTE, London, W.1, writes: This needle-head is a modification of that on the Stevenson needle, and presents the following advantages: (1) its "nutmeg-grater" surface scarifies the venous intima and allows a more perfect thrombosis than when a sclerosant only is employed; (2) gentle manipulation of the pliant shaft will traumatize the intima

Enlarged View

Bell & Croyden, London

without unnecessary damage; (3) the rocket-shaped nose of the needle facilitates the entry of this instrument into the vein. The shaft is usually 12 in. (30 cm.) long, and it is fitted with a "record" needle mount.

This instrument was made for me by John Bell and Croyden, Wigmore Street, W.1. I am indebted to Mr. Proudfoot for his patience and interest, and for the many specimens of this needle constructed before I was finally satisfied.

The Australian Commonwealth Director of Tuberculosis, Dr. H. Wunderly, believes that Australia could wipe out tuberculosis in 20 years if sufficient money were available. After examining the conditions in each State during the past six months, he has presented a report on the incidence of the disease to the Minister for Health.

Reports of Societies

RUPTURE OF CERVICAL INTERVERTEBRAL DISK

he subject for discussion at a meeting of the Section of Neurology of the Royal Society of Medicine on March 4 was rupture of the intervertebral disk in the cervical region. Dr. C. FORSTER-DROUGHT presided.

Dr. W. RUSSELL BRAIN said that the problem presented itself in patients who complained of symptoms of irritation of a posterior root in the cervical region, or of compression of the spinal cord in the neck, or in some cases of both. Some had a protruded intervertebral disk without arthritis, some had protrusion with arthritis, and some had arthritis without protrusion; the protrusion might be cartilaginous alone or both arthralgous and bony. The condition might be the result of trauma or it might be associated with chronic inflammation.

Disk protrusions were common in the cervical and lumbar regions, rare in the thoracic. Both cervical and lumbar regions ad greater mobility than the thoracic spine, and were specially exposed to trauma—in the lumbar region by strains due to weight-lifting or by falls on the buttocks, and in the cervical region by the effects of violent movements of the head. In the cervical spine the intervertebral disks were larger, relative to the vertebrae, than in the lumbar region. The posterior longitudinal ligament extended opposite each intervertebral disk, but did not reach the disk margin. If the central fibres were ruptured the disk protruded backwards in the mid-line, but if that did not happen or the disk protruded somewhat to one side it tended to extend laterally.

No doubt the earliest changes were vascular. The veins were the first vascular structures to be compressed, and since the flow in the veins was upwards the effect of compression was to produce oedema of the segments of the spinal cord immediately below the site of compression. The first effect of an anterior or antero-lateral protrusion would be an oedema of the anterior or antero-lateral areas of the cord at the site of compression and in a few segments immediately below. It was an interesting point whether the arterial blood supply also suffered; on general grounds it would be expected to suffer after.

Clinical Findings

Dr. Brain illustrated his further remarks with ten surgically verified cases, from one of which post-mortem material was also available. Most of the ten were middle-aged or elderly; only two were under forty. Only two had symptoms of the root irritation type alone; in the remaining eight the spinal cord was compressed. These numbers did not represent the relative frequency of the two clinical pictures. Trauma appeared to have been a factor in only two of the cases; osteoarthritis of the cervical spine was present in at least seven and might be fairly diffuse or limited to the articulations adjacent to one intervertebral disk. In one of these patients protrusion occurred during pregnancy, which was interesting in view of the relation of pregnancy to herniation of the lumbar intervertebral disk. Patients in whom trauma was an important factor seemed to be, on the whole, younger than those with osteoarthritis and more likely to develop root irritation than compression of the cord. The site of the disk protrusion was between the fifth and sixth cervical bodies in five of the cases, between the fourth and fifth in two, and in the other three cases it was between the second and third, the third and fourth, and the sixth and seventh, respectively.

Four principal ways in which the protrusion might manifest itself could be distinguished: an acute onset of symptoms, especially pain, involving the neck and one upper arm; insidious and perhaps remittent onset of the same character and distribution; insidious onset with root symptoms referred to one upper arm, together with evidence of lesion of the spinal cord; and finally, and much less commonly, there was the insidious onset of a progressive spinal cord lesion alone. The acute onset of symptoms involving the neck and one upper limb seemed often to follow trauma. The history of compression of the spinal cord

was quite short in a number of cases; in five of the ten patients it varied from two to nine months; others had a history extending over two or two-and-a-half years, and in one case ten years.

The most prominent symptom was pain, usually described as shooting or burning in character, and sometimes as agonizing. Sensory loss was usually slight and patchy, involving cutaneous rather than deep sensibility. A severe degree of muscular wasting, weakness, and hypotonia was uncommon. When the cord was involved above the cervical enlargement the signs of a pyramidal lesion were evident in all four limbs. One conspicuous feature was the frequency of wasting of the small muscles of the hand. In eight of the nine cases in which the cerebrospinal fluid was investigated some abnormality was found.

As with herniated lumbar disks, recovery from the symptoms of root irritation might follow conservative measures. Prolonged immobilization should be tried; operation should be carried out in those comparatively few patients who suffered from persistent pain in the neck or upper limb or from serious muscular wasting and weakness, or from spinal compression.

Surgical Approach

Mr. G. C. KNIGHT spoke of the importance of the relation of mid-line protrusion to the anterior spinal artery. Thrombosis of the anterior spinal artery in the lower part of its course was likely to have an ascending effect on the cord. He had seen a permanent paraplegia result from thrombosis in that artery. In true protrusion there was evidence of a progressive tendency towards herniation. The protrusion might increase in size and tend to involve more and more of the cord. He had seen three cases which appeared to form a localized spondylitis deformans, and in one case the bony changes in the spine were unilateral. In a traumatic case where there was possibly displacement of the disk as a whole pain could be felt not only in the usual localities but in the supraclavicular and suprascapular regions, and sometimes even in the precordia, leading to a misdiagnosis of the condition as coronary disease. Determination of which root was involved was better based on the paraesthesia than on the distribution of the pain.

Myelography was valuable at all levels. The best treatment for any protruded disk was "a long waiting list." Care should be taken not to operate on these cases unnecessarily or too soon. Rest in the position of greatest comfort to the patient would cure or relieve the majority. Flexion of the head away from the side of the lesion was usually the most comfortable position, but occasionally the opposite might be true. Manipulation was dangerous in disk protrusions. The indications for operation were fairly clear-cut. In a state of established compression, operation was indicated after conservative treatment had failed. He discussed the operative procedures. The single root compression could be tackled adequately by hemilaminectomy. In cord cases a full laminectomy was required.

Dr. J. W. D. BULL gave an interesting survey of the anatomy of the subject. On examining the size of the lower cervical canal the distinction from the lumbar canal was very striking. The tumour in the lumbar disk, when there was maximum protrusion, might be compared to the size of a cherry; on the other hand, in the cervical disk, it was about the size of a red currant. In radiographic examinations it was advisable to take four projections: the standard antero-posterior and lateral, and also two oblique. The antero-posterior view should be taken last after having seen to what extent the vertebral bodies were angulated in the lateral views. So far myelography had not helped very much in the diagnosis of ruptured cervical disk.

Conservative Treatment

Dr. ALDREN TURNER spoke in favour of conservative treatment. His remarks were based on 46 personal cases, in all of which there was pain at the back of the shoulder and down the outer side of the arm, and in some of the cases in the neck and the upper part of the chest. On examination, pain was accentuated by movement of the neck. Neurologically they all showed some signs of interference with function. Very few had radiological evidence of osteoarthritis. None of these patients was operated on. One of them was lost sight of; the

other 45 were followed up until the pain was better. They were treated in bed with four or five pillows below the neck, a sling on the arm, and a mild analgesic. Within less than three weeks 31 were relieved of the pain, and within four weeks a further 9. The remaining 5 were more resistant, and it was from 5 to 12 weeks before the pain ceased. Although the pain was relieved the paraesthesia continued, and he believed might continue for weeks and months. It was as well to warn patients of this fact.

In some further discussion Mr. J. E. A. O'CONNELL said that the average lumbar disk was 25 times as heavy as the average cervical one; nevertheless, quite small cervical protrusions had been known to produce severe clinical symptoms and signs. There were, in his view, four groups of cases of cervical disk protrusion: (1) Cases with cervical and brachial pain, the signs and symptoms showing themselves in the distribution of one cervical root. In this group, with conservative treatment, the prognosis was very good. He had seen 50 cases, of which only one underwent operation. (2) Cases in which at the onset there might be only neck pain and pain in one limb, but symptoms and signs of cord compression then appeared quite suddenly. He had had four cases of this kind in which he had removed unmistakable protrusions which were severely affecting the cord, causing not only compression but contusion as well. (3) Cases in which there was evidence of a severe lesion in the cervical cord developing acutely after trauma. (4) Cases of minor injury to the cervical cord associated with head injury. The features of these cases were stiff neck, weak limbs, and characteristic reflex changes, especially interference with the radial reflex. The lesion responsible he believed to be a cervical disk protrusion.

PSYCHO-ANALYSIS IN HOSPITAL

At a meeting of the Section of Psychiatry of the Royal Society of Medicine on March 9, Prof. Sir DAVID HENDERSON presiding, a discussion took place on "The Application of Psycho-analytic principles to the Hospital In-patient."

Dr. JOHN RICKMAN defined the aim of psycho-analytical therapy as being to enable the patient to disclose as fully and freely as possible the history of his development, including that of which he had been unconscious. This disclosure the doctor must meet with sincerity of purpose and dispassionately, and he must not lose patience in the face of failure. These qualities were also prerequisite for research. Discovery of the cause and solution of the problem of mental pain were not possible unless the patient experienced relief of suffering in the course of treatment, then he would co-operate in both research and therapy. "No research without therapy; no therapy without research." Invariably there was a strong but unconscious tendency on the part of the patient to defend himself against the research, and this defence process affected both patient and doctor, for if the latter had not worked out his own past experience he would unwittingly co-operate with the patient's defences in greater or less degree, thereby nullifying both the investigating process and the content of the therapy. The aim of psycho-analytical procedure was to facilitate the patient's re-experience of the uncompleted and unconscious emotional situations of the past.

In this, Dr. Rickman went on, there was nothing incompatible with the exhibition of sedatives, shock therapy, surgical interference with the brain or other organ, nor even with the restriction of social locomotion (certification). All these could be pursued along with psycho-analytical therapy, provided—a most important proviso—that every event was referred back to the broad kind of social relationship between doctor and patient known as transference. In the psycho-analytical treatment of the hospital in-patient complications arose from other simultaneous doctor-patient relationships—with the medical superintendent and the house-physician, for example, as well as with the analyst. The role ascribed to each of these persons in the patient's fantasies had to be discerned separately, and it might well happen that the patient would play off one doctor against another, so that the situation became exasperating. But in the long run it would work out satisfactorily if there was co-operation between the analyst and the other doctors concerned.

Relation of Analysis to Other Treatment

Dr. E. STENGEL said that psychiatry could not afford to neglect any approach which promised to contribute to the understanding of mental phenomena. Most cases in mental hospitals were not accessible to psycho-analysis in the ordinary sense, and what could be practised was in the main applied psycho-analysis. Psycho-analysis was thought of too frequently mainly as a therapeutic procedure, and the fact was overlooked that its contribution to mental science consisted of certain fundamental formulations. There was still a tendency amongst psychiatrists to judge the significance of psycho-analysis from its value as a therapy, and to forget, as Ernest Jones had put it, that psycho-analysis had provided psychiatry with an interpretive, a dynamic, and a genetic approach.

He had found it particularly helpful in cases of schizophrenia with remissions to study the patient's reaction by the application of psycho-analytic principles; this had helped him in arriving at a correct assessment of improvement. Dr. Stengel added that the understanding of mental illness did not preclude the possibility that it was an organic disease. On the other hand, the organic nature of the illness did not imply that it could not be influenced psychologically. It had been said that the neurological approach to mental illness, from which the primary clarification was expected, was incompatible with psycho-analysis. For his own part, he saw no difficulty in combining the neurological and the psycho-analytical approach. Some of Freud's concepts had much in common with those of Hughlings Jackson. Psycho-analysts did not claim a monopoly in their approach, but they did claim that for the solution of a great number of scientific problems it was indispensable, and they looked forward to the time when more trained psycho-analysts would work in mental hospitals.

Dr. CLIFFORD SCOTT gave a lengthy and detailed account of the application of psycho-analysis to a manic-depressive female patient at the Cassel Hospital in 1936-8. This patient, who was aged 20 when treatment began, was subject to emotional outbursts in the course of the treatment, but there was eventually an improvement in behaviour and certain homosexual fantasies gave place to normal sexual inclination. After discharge from hospital, treatment was continued for eighteen months, and when last heard of two years ago the patient was well. In such cases, if time was available, if colleagues were co-operative, and if psycho-analytical methods were persistently used, great improvement could be achieved and much good material from the point of view of psychological research would become apparent.

Advantages of Institutional Treatment

Dr. W. H. SHEPLEY agreed that there were certain disadvantages in treating patients analytically in an institution, particularly where the patients were in contact with other doctors, but the advantages far outweighed them. One advantage was that doctor and patient lived in the same community and were familiar with the same events—events which formed an important element in the patient's dreams. There were certain patients who could be treated only by physical methods, such as insulin or shock therapy, and only by resort to physical methods did the patient become accessible to psycho-analysis. He held that the remissions obtained by physical methods of treatment were not satisfactory; in his experience relapse invariably occurred if reliance was placed upon such methods alone, but when the patients had been made accessible to psycho-analysis and treated over a long period—a year or more—subsequent relapse might be avoided. Many of the patients themselves were acutely aware that physical methods alone meant ultimate relapse. It was an advantage in securing the patient's co-operation if he knew that psycho-analytical methods were undertaken to support the favourable results of the physical therapy.

Dr. IRENE YATES said that there were difficulties in treating patients in the wards, but with patience and strict honesty in approach they could be overcome. The psycho-analyst must be prepared to explain to the patient why he was doing certain things. Respect should be paid also to the patient's own "tempo" both in hospital management and in psychological treatment. The patient himself would often tell one what to do and what not to do. "I feel as if I had been run over

by a train," said one woman, "and cut to pieces. Leave me alone in bed and I shall come together." Matters should be allowed to unfold slowly, the psychotic patient being allowed to talk his own language, and the analyst talking that language too.

Dr. C. R. BIRNIE said that in the treatment of psychotic patients by psycho-analysis a more active type of therapy was necessary than was usually countenanced by the Freudian school. A point to be borne in mind was that in the attempted psycho-analytical treatment of patients in mental hospitals the situation was liable to become complicated because in the fantasy of the patient the nurse might become the "mother" or "sister" as the case might be. It was very desirable, therefore, to have mental hospital nurses who could appreciate the psycho-analytical view.

Dr. E. H. ROSENBERG said that the use of the psycho-analytical method of investigation would throw light on a number of problems. It was important in psychotic illness to make some estimate of how far the morbid process was capable of arrest. She regretted that the discussion had not emphasized more the administrative difficulty which arose in treating hospital in-patients.

Dr. E. BIERER said that in modern mental hospitals psycho-analytical principles had been understood for many years, and he thought the openers had been preaching to the converted. Dr. Stengel had criticized the "short" method, but how was it possible to apply in practice in a mental hospital the full unabridged Freudian analysis?

Change of Attitude

Sir DAVID HENDERSON, the President, said that while the attitude of psychiatry might have changed, that of psycho-analysis had changed also. Psycho-analysts had developed a philosophy which was of extreme importance, but viewed as a therapeutic procedure he had no hesitation in saying that there was still wanting a technique which would give results in mental hospitals. Psycho-analysis as a therapeutic measure in mental hospitals had not justified itself to the extent that had been hoped. He was not gainsaying the contribution which Freud and others, including in this country Ernest Jones and Edward Glover, had made to the knowledge and understanding of the personal equation, but he still believed that from the point of view of therapy, taking it all through, it was a most disappointing procedure. Dr. Stengel was trying to get the best of both worlds, suggesting that physical and psycho-analytical methods needed all to be balanced up together. The plea for such integration was certainly significant of a change of attitude.

Dr. RICKMAN, in reply, said that if short methods were employed in mental hospitals they should be carried out only by those who were trained and kept refreshed in full psycho-analysis. Dr. STENGEL thought that those who practised the short treatment should call themselves psychotherapists; there was nothing wrong in the name. Dr. CLIFFORD SCOTT also urged that only those who had had experience of psycho-analysis extending over a long period should be permitted to use the abridged treatment.

AETIOLOGY OF INFLUENZA AND THE COMMON COLD

A meeting of the Medical Society of London on March 8 was devoted to a discussion of the aetiology of influenza and the common cold. Mr. W. E. TANNER, the president, was in the chair.

Dr. CHRISTOPHER H. ANDREWES, F.R.S., said that such a discussion must take note of a number of upper respiratory diseases among which influenza and the common cold stood out more or less clearly. The others included the affection unfortunately named atypical pneumonia and febrile catarrh, which the Americans had recently been referring to as undifferentiated acute respiratory disease, or "A.R.D." This was an infection usually febrile, more severe than the common cold, and probably having as one of its manifestations an exudative pharyngitis and tonsillitis with which streptococci were not associated; its incubation period was apparently five to seven days.

Epidemic influenza might be caused by one or other of two serologically unrelated viruses known as A and B. There was good reason for thinking that they covered most of the epidemics, though in some epidemics it might be difficult to demonstrate the presence of either of them. He exhibited a chart prepared by Dr. S. D. Collins, of the U.S. Public Health Service, showing the distribution of outbreaks of influenza from 1920 to 1943. The distribution appeared to be entirely irregular until it was recognized that there were two viruses concerned. Immunity to virus B lasted rather longer than immunity to virus A. Outbreaks of influenza in which virus A was concerned might be said to occur in a two or three years' cycle, whereas those in which the aetiological agent was virus B occurred in a cycle of four to six years, but it was not yet known why epidemics arose when they did. The irregularities in epidemics might be explained by variation in the antigenic structure of the virus, and when a little more was known about its structure it might be possible to predict epidemics with more certainty.

Certain evidence suggested that a new strain of influenza might travel about from country to country. A recent paper by M. D. Eaton (*California Medicine*, 1947, 67, 234) in which the seasonal incidence and geographical location of outbreaks were discussed made it difficult to avoid the conclusion that A and B viruses travelled about the world. The World Health Organization had established an influenza centre which would receive strains from laboratories in all countries, compare them antigenically, and try to build up a picture of influenza as a world-wide phenomenon. It was possible that the pandemic of 1918-19 was not peculiar in its rapid spread all over the world; in other years epidemics might spread with equal rapidity, though with less virulence. Immunization against influenza looked promising two years ago with good results reported from the United States, but last year there was complete failure both in the United States and in this country. This failure was probably due to the appearance of a variant of influenza A, antigenically remote from the strains used to make the vaccine.

Common Cold

Much less was known about the aetiological agent of the common cold. It was possible to transmit colds to human volunteers with filtrates from the nasal washings of cold sufferers. Dr. Andrewes spoke of the results of such transmission to volunteers at the Common Cold Research Unit at Harvard Hospital, Salisbury. Filtrates produced in about half the subjects symptoms of varying degrees of severity, from the really "heavy" cold to something which could hardly be called a cold at all; 50% of the subjects were immune. It was believed that they had succeeded in transmitting colds in series from one person to another, and therefore some confidence was felt that the agent was a virus. He had an open mind on the question whether certain colds might be due not to a filtrable agent but to bacteria—whether there might not be the "pneumococcal colds" of which their bacteriological colleagues spoke.

The incubation period in the production of a cold was, as a rule, two or three days, though this was in curious contrast to some reports from America, where quite a number of different groups had recorded incubation periods of less than twenty-four hours. It seemed fairly certain that the mere bringing together of the virus and the susceptible person was not enough to produce a cold. It was not known what the other factors were nor how important they might be. Was it possible that a great many people carried the aetiological agent of a cold in their noses until something happened to upset the balance between host and parasite and a cold followed? He had no doubt that specific immunity did play a part, but he also had the feeling that non-specific factors might dominate the situation in this country. Efforts to grow the virus in eggs and to infect experimental animals were continuing, but the whole picture remained for the present highly confused.

Epidemiological Characteristics

Prof. C. H. STUART-HARRIS said that of the group of respiratory tract disorders only two were sufficiently defined—namely, the common cold and influenza. The common cold could be described as a relatively trivial ailment, usually afebrile, but

certainly one of the most troublesome that afflicted mankind. Many conditions had been grouped under "influenza." At least four different entities, partial entities, or syndromes were recognized—influenza, the common cold, febrile catarrh, and atypical pneumonia. Since the viruses of influenza were most accessible to study, more was known about them. Influenzas A and B, though clinically indistinguishable, corresponded reasonably closely with what was reported of past epidemics. There was no reason to think that the two were dependent on each other or connected in the immunological sense. During the last fifteen years there had been three fair-sized epidemics of influenza A, and in between there had been certain "rumblings" and occasionally rather sharp waves due to influenza A or sometimes to influenza B, and now and then influenza B predominated. The cycle of two or three years had been fairly well obeyed by influenza A; the cycle of four to six years for influenza B had been obeyed in the States, but less certainly in this country. The clinical picture was relatively uniform, the emphasis always being on symptoms of a general febrile character—headache, shivering, malaise, and anorexia. Among respiratory symptoms cough was most frequent; the coryza was not to be confused with that attending the streaming cold. In any outbreak, and particularly in the years of localized outbreaks, a proportion of cases did not yield serological evidence of either virus. It was characteristic of most outbreaks of influenza that the cases remained uncomplicated.

Febrile Catarrh

Localized outbreaks of febrile catarrh, Prof. Stuart-Harris continued, had been recorded frequently in the past, and cultures had been shown not to yield influenza virus. No one had yet succeeded in recovering the aetiological agent in this disease, but there were certain broad facts about febrile catarrh which were interesting and justified the view that it was a distinct entity or group of entities. In an Army camp it was found specially to attack the new recruits; the incidence among the seasoned troops was much lower. On the other hand, the seasoned troops were attacked by influenza. Most cases of influenza came on quite suddenly, whereas febrile catarrh had much less commonly an acute onset, usually starting with a little cough or cold, the fever coming on a day or two later. Sore throat, hoarse voice, and substernal chest pain were common. But the clinical picture of febrile catarrh was not uniform and some cases resembled streptococcal tonsillitis. As for atypical pneumonia, this was relatively rare in Great Britain, and there were only sporadic cases among British troops during the war at a time when the Americans were experiencing considerable outbreaks.

Secondary Invaders

Dr. FREDDY HIMMELWEIT said that a number of pathogenic organisms, and especially pneumococci, had been looked upon, ever since the discovery of the influenza virus, as secondary invaders, responsible only for complications which might vary from individual to individual and from epidemic to epidemic. In his view, however, these secondary invaders might not only aggravate the primary infection but play an essential part in causation. He believed that they facilitated infection by the virus by destroying the inhibiting action of the mucin of the upper respiratory tract.

The discussion, in which Sir JAMES WALTON, Dr. WILFRID OAKLEY, Dr. GEORGE GRAHAM, and Dr. CARLYLE LYON took part, resolved itself largely into a recital of personal experiences in combating colds. Sir James Walton said that he had found *Strep. viridans* vaccine highly protective. Mr. V. E. NEGUS mentioned nasal defence. The reason why some people never had colds was because of the efficiency of their ciliated epithelium. The cilia were very resistant, but could not work without a covering of mucus.

Dr. J. B. W. ROWE suggested that in the case of the people of Spitsbergen, who were said to get infection only when the ships visited the island in the summer and to be free from colds during their isolated state in the winter, the reason for the manifestation might be the change of diet which followed the arrival of the ships with food. Some allergic factor might play a part in the aetiology of the cold. Dr. W. H. BRADLEY remarked that the winter of 1947-8 had been phenomenal in

the fact that deaths from influenza had been the lowest on record and deaths from pneumonia much lower than usual. On the suggestion just made, was it possible that this had anything to do with the food we had not eaten? Mr. JOHN BUNYAN said that a large number of people suffered from gingivitis, which might afford a foothold for the invasion of the virus.

Dr. ANDREWES, replying to the discussion, said that Dr. Himmelweit's theory needed a good deal of further consideration before it could be accepted. He did not think at this stage they could justifiably reverse their opinion on the relative parts played by the virus and bacteria in causing these infections. The one thing that was clear about vaccines was that many people placed implicit faith in them. In the United States a mixed catarrhal vaccine was given to a number of students and records were made of the incidence of colds among them during the following year. Of those who received the vaccine 55% reported benefit. But a corresponding number had received not the vaccine but a saline injection, and an even larger proportion of these students reported benefit, and some of them wrote to the doctors concerned asking whether they could be told, in confidence, the formula of the preparation which had proved so effective.

CONTROL OF POST-PARTUM HAEMORRHAGE

A meeting of the North of England Obstetrical and Gynaecological Society was held in Manchester on Feb. 6 with the president, Mr. J. E. STACEY, in the chair.

Mr. K. V. BAILEY (Manchester) showed a film illustrating a safe manoeuvre for stimulating the uterus to retract in cases of third stage and post-partum haemorrhage, and also an additional method of infant resuscitation. After mentioning the dangers and disadvantages of the usual methods of controlling the uterus, of fundal massage, and of expression of the placenta, Mr. Bailey demonstrated a method of stimulating the uterus by gentle stretching of the lower segment which was achieved by stroking the uterus upwards with the ulnar border of the hand. In some cases when the infant required resuscitation he advocated laying it face downwards on the palm of the left hand with its head hanging down to drain the air passages. Artificial respiration was achieved by throwing the whole child upwards for about three-quarters of an inch, inspiration being encouraged during its "flight" and expiration when it settled back on the hand. Both procedures were discussed by several members of the society, and there was general agreement that stretching of the lower segment by various methods was of value in the control of post-partum haemorrhage.

Dr. S. BENDER (Liverpool) discussed a case which presented as tuberculosis of the cervix and which macroscopically resembled carcinoma of the cervix. Dr. A. A. GEMMELL (Liverpool) described a case of fibroid in the cervical stump after subtotal hysterectomy. Six other published reports of this condition were discussed, and Dr. Gemmell suggested that incomplete removal of ovarian tissue at the time of hysterectomy might favour the subsequent development of fibroids in the cervix, and that the rapid growth which appears to be a feature of these fibroids might be due to early degenerative changes consequent upon a poor blood supply. Finally Prof. D. DOUGAL (Manchester) gave an account of an interesting case of carcinoma of the body of the uterus and fibroids treated with radium and subsequently by hysterectomy.

The sixth and final dinner meeting of the 1948 session of the Chelsea Clinical Society was held on March 9 at the South Kensington Hotel, with the president, Dr. Neil MacLay, in the chair. There were nearly a hundred members and visitors present to hear a discussion on "Medical Experiments in Nazi Camps" opened by Major A. Keith Mant, R.A.M.C., whose work with the British War Crimes Commission made his contribution particularly valuable. An interesting discussion ensued in which Dr. Pitts, Mr. Gwynne Evans, Dr. Stuart Webb, and Dr. Eckenstein joined, and finally Major Mant replied. The annual dinner of the society will be held on May 11.

Correspondence

Bad for the Public

SIR.—None can tell for certain what made so very many in the profession say "No" in the plebiscite, but I am quite unable to believe that it was no more than zealous support for the Association's four points or even their immediate implications. There must be many besides me whose hopes, raised a little by that impressive demonstration of unity, will fall below zero unless the declared basis of our objection is broadened and deepened.

I believe the majority was so great partly because a free profession, with a great record of service in peace and war and almost a monopoly in knowledge and understanding of medicine, has been treated as so much technical labour, and partly because it sincerely believes the Act to be in many fundamental respects a disastrous blunder. Mr. Bevan rightly observes that our quarrel is not at bottom with him: it is with the plan, and it goes back to the start. No Royal Commission, invited to examine the country's medical services and to plan their extension and ultimate perfection, could ever have recommended anything like this Act. It has never been a single-minded endeavour to give the people first-class medical care—let alone health. It has been from the outset largely concerned to implement "Assumption B" on an appointed day and to equalize medical attention regardless of quality. Its motives and ideals are not medical or hygienic but political.

The result is a plan which bids fair to reserve the practice of real medicine and surgery to the hospitals, while outside the practitioner plays his part in the ordering, repeating, and dispensing of medicines, the directing to specialists, and above all in that "careful certification" of the Beveridge report.

Mr. Bevan does not blush to suggest that we take on 4,000 or more potential patients—blind, seemingly, to the fact that he who does so must bid farewell to the practice of medicine. No reward is offered for work performed or for excellence of any kind. Good honest private practice is made as difficult as possible. Charlatanism is, to put it mildly, in no way discouraged, and the temptation to see other men's patients behind their backs is greatly increased. Collective bargaining and trade unionism, alien to a free profession, clearly await us. None of the benefits the practitioner might have hoped for—ancillary services at call and better access to hospitals—is to be his, at least for years to come. Even the queerly named "health centre" is indefinitely postponed. Finally, we are to be involved in a fiasco—the opening of a non-existent show for which all have been compelled to buy tickets.

All this is at least as bad for the public as for us. What is bad for medicine and for the doctor cannot be good for a medical service and those it serves, nor can it be supposed to be good for the credit of Parliament or the Government. The profession has expressed disapproval of the Act, and I believe it means what it says. The Act is bad. To have a stand-up fight about it on four points, none of which touches the quality of medical practice or the place and function of the general practitioner in the projected service, seems to show a distaste for facing realities almost equal to that of Parliament itself. The whole future of medicine is at stake. Are we not strong enough and brave enough to demand postponement of the relative parts of the Act and a constructive reconsideration of the medical service on a medical basis?—I am, etc.,

London, N.W.3.

LINDSEY W. BATTEN.

Freedom of Consultants

SIR.—The professional freedom of consultants is vital to the public, for it is to consultants that disputed points of certification and other questions of controversy are ultimately referred. Great play has in the past been made of the desirability of a detached position for the Royal Colleges from which they may descend in order to inaugurate a compromise between the Minister on the one hand and the B.M.A. on the other. This argument is allowable so long as questions of principle are

not involved, but no man with a true respect for the integrity of medicine will compromise upon this vital point of consultant freedom.

The political mind is distinguished from the scientific mind by its blind spot where principles are concerned and its obsession with manipulation and manoeuvre. All actions and statements at the present juncture must be judged by the profession on this issue of principle and on this alone.—I am, etc.,

London, W.1.

GEOFFREY BOURNE.

The Minister's Confusion

SIR.—The statement recently made in Parliament (Feb. 9, by the Minister of Health shows a deplorable ignorance of what precisely is entailed in the sale of goodwill of a medical practice (see *Journal*, Feb. 14, p. 323: "The Government regarded it as inconsistent with a civilized community and a reasonable health service for patients to be bought and sold (my italics). That existed in no other country, and was a blot on our medical system. . . . So far as the Government was concerned there could not be any question that the health service must not contain the buying and selling of public practices").

Apparently the Minister still confuses the buying and selling of a farm (where the cows, pigs, hens, etc., even if dissatisfied with the newcomer, are not free to select another farmer) with the buying and selling of the goodwill of a medical practice (where the patients, if dissatisfied with the newcomer, are quite free to select another doctor). It must be stressed that no patients are in any way bought or sold. It is merely the goodwill—i.e., the probability (no more) that a proportion, perhaps 66-90% of the patients of the retiring doctor will give the incoming doctor a trial (and then not necessarily remain one of his patients). Private patients remain free, as always, to change their doctor at will. Panel patients are actually informed officially of the change in practice, and they are therefore at liberty to select a new doctor within the next month; and after that time they can of course change in accordance with N.H.I. regulations.

The Minister's statement was made, presumably after due forethought, in opening a Parliamentary debate. It was not subsequently retracted or modified. It was made by the Minister, who has held office—the same office—for two and half years, and therefore has had ample time to discover the true facts. Indeed it was his bounden duty so to do before initiating the N.H.S. Act. He has failed in this duty.

Owing to his confusing the buying and selling of the goodwill of a medical practice with the buying and selling of patients he has misled himself and Parliament. He has piloted an Act through Parliament based on his misunderstanding of a fundamental principle. In consequence of his error many provisions (which would otherwise have hardly seemed necessary) have been incorporated in the Act, or regulations to be made under it, which are repugnant to a big majority of the medical profession.

If the Minister could clearly grasp this fundamental distinction then his objections to the buying and selling of goodwill might well be overcome, and he could then explain to Parliament that he had misled them and recommend that the amendments so earnestly desired by the profession be reconsidered.

If the right to sell goodwill remains, the severe penal clauses designed to prevent concealed sale of goodwill, ambiguity over partnership agreements, direction (or negative direction), and perhaps even basic salary (for the main admitted object of this is to enable a doctor to subsist while building up a practice)—all these difficulties would be settled. This would leave only the question of appeal to the courts, the equitable implementation of the Spens Report, and freedom to publish to be settled.

Regarding appeal to the courts, I feel that under the Act as it stands injustice to any practitioner is unlikely. Nevertheless it is hard to see why the Minister should object to the findings of the Executive Committee and of his Tribunal being challenged in the High Court. If the proceedings in these investigations have been fairly conducted and a just verdict passed, then surely the High Court will merely confirm the decision; and if the decision is reversed then there must at least be doubt about the practitioner's guilt. The Minister's refusal to allow appeal to the Courts suggests that he is not really so sure of justice being done by the Executive Committee and Tribunal.

I consider freedom to publish letters, articles, or books on all medical matters (including clinical subjects and the organization and administration of the Health Service) without having to seek permission from individuals or authorities should be specifically incorporated in the amending Act of Parliament. Mr. Bevan's reply on Feb. 12 to Col. Stoddard-Scott on this subject appears inadequate, as it is not binding on his subordinates or successors.

Regarding remuneration, though a capitation fee is not intolerable I personally would prefer payment per item of service—thus resembling private practice, which is usually preferred by patient and doctor alike. Also it might diminish unnecessary work inflicted on doctors by Government authorities. If the Treasury had to pay, say, 3s. 6d. for a consultation and 1s. for a certificate each time a hyperthyroid patient had to see the doctor for no reason other than a renewal of a milk priority it might soon be found possible to require these at longer than one-monthly intervals. Or a "repeat medicine as required" prescription might after all be acceptable for mag. trisil. co., etc., for a gastric-ulcer patient or insulin for a diabetic. Nor might a doctor's consultation be necessary to confirm addiction to tobacco.

It is generally conceded that in the past private practice has partly subsidized panel and club practice. Now it seems likely our income will be reduced by 10-25%, our expenses increased by 5-10%, and our work increased by 10-25%. This is hardly as recommended by the Spens Committee.—I am, etc.,

Rugby.

R. PRESTON HENDRY.

Leavening the Commonplace Mind

SIR,—It is not clear from the last paragraph of Dr. F. M. R. Walshe's excellent letter (Feb. 28, p. 407) whether he advocates a firm stand against the National Health Act in its present form or against any change in the *status quo*. That the latter is the more probable is suggested by his reference to "a retrograde political ideology" and later "a ruthless and levelling force" which must be resisted. The pleasure engendered by the force and clarity of his exposition of "first things first" is apt to lull us into accepting not only the diagnosis, with which few of us could disagree, but also the treatment prescribed.

Wilfred Trotter said (*Journal*, July 17, 1926): "In biological inquiry an abstract conception, though professedly no more than a convenient summary of experience and constantly subject to the censorship of facts, is apt to acquire a quasi-vitality of its own through which it loses its immediate dependence on experience and comes to dominate instead of serving. The danger arises not so much from the extreme cases of conceptions which easily show as flagrantly inconsistent with facts but from ideas primarily good and sound which have been endowed with a prestige that in their very nature they could not deserve." If we take the liberty of substituting the word "sociological" for "biological" we find these remarks most apt to the present trend of events.

Socialism, though originating from "ideas primarily good" appears to-day to be an abstract conception flagrantly impervious to the censorship of at least some of the facts, one such being the impossibility of "nationalizing conscience." It certainly appears in our own case to promise to dominate the profession rather than serve the community. We are tempted to believe, therefore, in our moral obligation to resist what Dr. Walshe describes as "a ruthless and levelling force" and what I have somewhat euphemistically called a "trend of events."

In filling in my plebiscite form I found myself on the verge of signifying approval, for though as it stands the Act contains many apparent and real injustices, incongruities, and absurdities which automatically make us revolt against it I had to confess that I found in it nothing iniquitous (using the word in its worst interpretation) except the extent of the power with which the Minister is to be endowed. It cannot be said that the present state of medicine from the patients' point of view contains no iniquities. However, the Minister's future power coupled with his recent provocative manner finally overcame my fear that the profession by its disapprobation might amend the Act out of existence.

If socialist ideology is an abstract conception which has acquired "a quasi-vitality of its own through which it has come to dominate instead of serving," the same may be said of our conception of the *status quo ante* which we call free enterprise. I do not deny that free enterprise is in itself an "idea primarily good," but it is a system in which its advocates also ignore the censorship of facts, the most important of which is the monotonous recurrence of

war with its attendant "corpses, cripples, rags, smithereens, and ruin," to use a phrase of Shaw's.

Though evolution is another abstract conception, one of its component experiences is the relentless revolt of the masses, which to-day faces us with concrete reality. I believe this revolt to be primarily directed against social injustice and the power of money. I believe this "levelling down" process, which feature of the revolt must be repudiated by the professional classes, is due, first, to a failure by the masses to distinguish between the hereditary money owner and excessively rewarded shareholder on the one hand and the successful business man or talented professional man on the other; secondly, it is due to a failure by the latter to recognize against whom the revolt is really directed.

It would appear, therefore, that two extremes of action present themselves for our choice. We can be reactionary and strive for an indefinite postponement of this Act or we can, after fighting for the four main amendments, accept the "inevitable" grudgingly and with docility. The former reaction would eventually be crushed by public opinion, the latter would show an inertia which, if followed by other sections of the community, would lead to communism as we now see it. Both lines of action would result in the death of the ethics, integrity, and intellectual freedom of the medical profession, the one murder, the other suicide.

I submit that there is a middle course capable of acquiring a real vitality of its own which would in time endow the medical profession with the prestige it could so richly deserve. In other words the future health service is going to be what we make of it. I suggest we exceed our present demands and insist on an altered executive whereby the profession would be more adequately represented and the supreme authority a council rather than one man. A united and contented profession with security for its own unassailable freedom, guaranteed by law, would be potentially the greatest power for good that this country has seen for a century. The "qualities of rare excellence" will be capable of removing the "imperfections" only through the medium of a comprehensive service. It is up to the profession as a specialized minority to reassert its place as an influential unit in the mass rather than submit to virtual extinction by fighting to the death outside it or by resignation. The commonplace mind is in dire need of good leaven. This must come from within.—I am, etc.,

Liverpool, 17.

ARTHUR S. WIGFIELD.

Adulation

SIR,—The general impression given by the very long letter from Dr. Stephen Taylor (March 6, p. 463) referring to the present Minister of Health repeats the phrase "but for him . . ." no less than three times in a single paragraph, which ends with the pompous phrase, "in battle, he will neither give nor ask for quarter."

Dr. Taylor's sincere but fulsome adulation of Mr. Bevan as a hero almost implies that this Minister can do no wrong and that it is really rather wicked even to criticize him and at a mild misdemeanour to hold a different opinion from his own. This quasi-religious tone applied to a Minister who, after all, is merely a man and a politician is as absurd as it is irritating and displays the sort of attitude which, carried to an extreme, might lead to the suggestion that a portrait of Mr. Bevan be placed upon the wall of every doctor's surgery. If we are to indulge in idolatrous adulation let us think of men and women who have been of some real service to the science and art of medicine.—I am, etc.,

London, W.4.

JOHN C. C. LANGFORD.

Why Compulsion?

SIR,—“If you declare war, you will lose.” Dr. Stephen Taylor (March 6, p. 463) is, on his own admission, a Labour M.P. “who happens also to be a doctor” [*sic*] and his prediction can be relegated to the category of propaganda of the “inevitable, bound-to-come” type to which Labour-Socialists are so addicted (cp. Dr. Stark Murray: “We are unquestionably going to have a Service which is free at the time of use”). It is sufficient to point out that the Australian medical profession in similar circumstances has successfully rejected a comparable Act.

His instance of the General Strike of 1926 is singularly unfortunate from the point of view of his argument. That event was an attempt by direct action to subvert the British Constitution and overthrow Magna Carta in favour of a dictatorship of the proletariat. It failed through the common sense of the

people. The National Health Service is a more subtle attempt to achieve the same end by fifth-columnry masquerading under the guise of constitutional methods; and please God it will fail also. If that is an incorrect reading of the situation, why the need for compulsion? Why is the patient denied the right to contract out of the Service? We are asked to believe at one and the same time (1) that this Act represents the will of the people, and (2) that the people must be coerced into it by the methods of totalitarian compulsion we have seen in action in Nazi Germany. We are told that the Service would not pay financially unless everyone contributed; that is to say, it cannot stand on its own feet by its own merits but has to be bolstered up by force. A "great Health Service" indeed! It stands utterly condemned out of the mouths of its own protagonists.—I am, etc.,

St. Germans, Cornwall.

W. H. SPOOR.

Change the Appointed Day

SIR.—Dr. C. H. Barber (March 6, p. 472) may find it alarming that so many of his confrères are dispassionately analysing the main points of difference between the Negotiating Committee and the Minister and finding themselves lacking that zeal for self-immolation which apparently animates him and the majority, but it is a factor with which he and they must reckon. Truly the points of difference are not the expression of sacred principles at all, but only the expressions of a desire, which is widespread in the profession, to avoid a full-time salaried service. This could equally well be achieved by adopting some ace-saving formula such as that suggested by Dr. Joan Wagstaff Feb. 21, p. 358)—namely, that the basic salary be designated an "expenses allowance" and that amending legislation be introduced to limit the Minister's power to vary this above the ceiling limit of such reasonably agreed minimum expenses as every doctor must incur. Dr. A. C. Mowle well says (March 6, p. 468) that this is the only point on principle which the Government can concede, and it will save the face equally of the Minister and the B.M.A.

I am not at all clear whether the wording of the resolution to be put forward to the Representative Body by the Council Supplement, Feb. 28, p. 29) is intended as an ultimatum to the Government, or whether it is intended as an olive branch to procure reopening of negotiations. If the latter, as I hope, say I suggest that it would be more helpful and more in accord with the hope of a settlement if the final clause were deleted and the Government simply invited to make it possible for the profession to co-operate in the new Health Service by making certain changes by the appointed day? I have no desire to reach, but neither have I any intention of allowing my pig-headedness to start me charging down a slope into the sea.—I am, etc.,

South Molton, Devon.

R. A. NASH.

Monotonous Repetition

SIR.—Thanks to Mr. Colm Brogan's article (Jan. 31, p. 209) even the merest tyro in politics can see his predictions being fulfilled in the arguments of favoured Labour M.P.s. Dr. Stephen Taylor's letter (March 6, p. 463) may seem mild in tone, but the litterite method is there for all to see. The main point is to keep telling your adversary with monotonous reiteration that he is bound to fail, and that resistance is therefore useless. By this tactic the enemy hopes to secure victory without a battle. I quote the relevant tactical repetitions from Dr. Stephen Taylor's letter. (1) "Any attempt to frustrate the law by extra-parliamentary means is bound to end in failure." (2) "In battle, he [Mr. Bevan] will neither give nor ask for quarter" (this to frighten the enemy). (3) "If the B.M.A. decides to continue the fight, the public will be gravely injured [sic] . . . and the ultimate defeat of the B.M.A. is certain." (4) He assumes that the public are entirely with the Socialist Party, and say that "for the public, defeat of the B.M.A. is certainly preferable to capitulation of Government and Parliament to the B.M.A." (5) "If you declare war, you will lose."

It seems that no Government has ever been holier than the present Government. No one was holier than Hitler. No German wanted to see Hitler defeated. No one in Britain wanted to see the present Government defeated! It is worth reminding Dr. Stephen Taylor and Mr. Bevan that in Australia

the doctors defeated the Socialist Government by refusing their services to the Government. The public did not suffer gravely. The doctor's prime duty is to serve his patients, and we can serve them and utterly ignore the efforts of the State to enter within the doctor-patient relationship.

In the General Strike of 1926 the workers who struck received no pay, because they were entirely dependent on payment from employers or the State, when strike-pay ran out. This was the lesson that the arrogant T.U.C. and the Labour Party learnt. The strike fizzled out in 11 days. Cardinal Bourne spoke against the immorality of the strike, which imposed considerable hardship on practically all the people in the country merely because the T.U.C. wished to gain their points.

We have the moral right to stay out of this Socialist State Service, and to keep the State from interfering in the doctor-patient relationship, by possessing our souls, our consulting rooms, and our practices. We shall still serve our patients, even if we have to treat them all as private patients. If we hold firm the State will have to climb down.—I am, etc.,

Slough.

N. C. HYPER.

Freedom of G.P.s

SIR.—It is rumoured that the Negotiating Committee will have to capitulate on the right to buy and sell the goodwill of medical practices because they will not receive the support of the Opposition in the House of Commons. If this rumour is correct, and if this attitude is going to be adopted by the profession at large, let me say most emphatically that it is a wrong attitude. We must realize now, and more especially with the result of the recent plebiscite in front of us, that we must press for an amendment of the Act as a united profession, and not rely on the support of any political party—we must be prepared to oppose the Opposition if necessary.

The whole of our freedom as general practitioners is at stake, and do not let us forget, especially those of us who are practising in congenial areas, that the freedom of the junior and future general practitioner is also at stake. The right to buy and sell the goodwill of our practices is the keystone on which our professional liberty is built. Surrender this and we have direction—negative direction, they say, but still direction. So long as we retain this right we can go where we like, practise where we like and are liked, and we can choose our successor to take over a practice which we have built up by our own efforts and which is very dear to us.

Take the case of a doctor who has worked hard for ten to fifteen years in a busy industrial area and then wishes to take a smaller and more congenial practice in another district. What chance will he have? In theory, as much chance as anyone else, but in actual practice not an earthly chance. And then there is the case of the doctor who will want to move to a better type of practice. How is this going to be attained? Suppose the owner of the practice dies—are we going to have compulsory billeting of the newcomer on the widow until he can find a house, to practise from? To pursue the matter further, if the sale of goodwill is abolished it will ultimately lead to the direction of the patient to other doctors who are less successful, because in any practice—be it private or State—there will always be goodwill, for each doctor will always attract a certain type of patient and repel another. If one wants to take a suitable partner or assistant, must this also be decided by the Medical Practices Committee?

The Negotiating Committee and the medical profession must not agree to the abolition of the buying and sale of goodwill, for if they do our freedom as general practitioners will go and we will become members of a full-time State medical service, be it Labour or Conservative in origin, and payment by basic salary or capitation fee and the right to appeal to the courts will mean nothing. We will be State servants and our future movements will be controlled by the State.

During the next few months we have a heavy responsibility, but we must shoulder it ourselves and realize that in so doing, in addition to preserving our own liberty, we are fighting for the freedom of our patients. Do let us remain united and not be side-tracked by fears which are without foundation. Tell the public what we stand for and we will have their support. All the individual patient is interested in meantime is—"Am I going to be allowed to retain my own doctor?"—I am, etc.,

Aberdeen.

DUNCAN McLELLAN.

A Fantasy in One Act

SIR,—May I call attention to the problem of the well-established G.P. of twenty or thirty years' standing, with a panel—usually built up, not bought—of under a thousand? Not on principle, not for politics, but from purely practical considerations many of these doctors must refuse service under the Act.

If the Service does not mean more attention for more people, it is not needed at all. If it does, the busy doctor and his harassed wife and household, already pestered from 8.30 a.m. to 11.30 p.m. with 'phone, bell, and messages, apart from night emergencies, already bolting meals almost invariably interrupted, already struggling with inadequate assistance to keep the house warm and clean—if it does, I say, the hunted leisureless doctor and his unpaid self-sacrificing wife must say "No" before coronary thrombosis says it for them. An eighty-hour working week and twenty-four-hour seven-day duty do not call for more sacrifice on the part of the doctors and their families but for some amelioration of their conditions of work. If the scheme is started before clinics are available to halve the doctors' clinical and administrative work it will prove a fantasy in one act, and, far from giving more doctors to the people, must deprive them of the services of some doctors who have so far been found sufficiently satisfactory to make them intolerably overworked.—I am, etc.,

London, N.E.

JOHN RUBRA.

State Control

SIR,—Now that the medical profession have shown by an overwhelming majority by the plebiscite that they reject the proposed service it is to be hoped that a repetition of 1912 will not occur and that some doctors will not, as the Cabinet puts it, "break away" and become blacklegs to the cause.

In the present panel system prescribing is done by a armulary, and, should a doctor order a proprietary preparation which to his own satisfaction and with his experience he has found to give better results than mist. A.B. or pil. X set out in the National Health *Formulary*, he will be a lucky man if the hand of authority does not descend on his head and an admonition given telling him he must not write his own prescription when mist. A.B. or pil. X is in the *Formulary* and would do. His independence to practise where he so wishes is taken away and he would merely become a slave to the supply and demand of a specified area. Has such a state of affairs ever been known in the history of medicine? Again, even if there was a right of appeal, to whom could the doctor appeal? The courts of law could only deal with appeals on a point of law—viz., interpretation of the Act—and should a special tribunal be appointed the odds are on the members of the same striving to uphold the Minister's decision.

Again, the doctors are offered "compensation." Was not the whole country promised payments of our post-war credits when hostilities ceased? Have we received them? If the present economic crisis—as it is doing—gets deeper and deeper into the morass, we will no doubt say "goodbye" to the payment of these credits. What guarantee can we possibly have of receiving compensation for our practices, etc.?

Mr. Bevan believes doctors will be discouraged by means of the basic fee from taking too many patients. Take a look at the present panel lists. A doctor is allowed 2,500 panel patients and another 1,500 if he has an assistant. In purely or mostly panel practices where the doctor has a full panel the number of patients the same doctor will have under the Health Scheme is at least 7,500 (allowing one wife and one child on the average for each insured patient). Even if the remuneration is alluring with such a number, can any doctor honestly say that he can give a first-class service to 7,500 souls, or be expected to do so? Such is impossible.

Let Mr. Bevan start his Service on July 5 with his 4,100 doctors, but let all those doctors who have now voted against the scheme stand fast by their guns, because no one, nothing, can survive that battery of power which the doctors have at their disposal. After July 5 let the doctors carry on on the present basis. Let them say openly to the patient, "I am not in the Service; I will treat you; you pay me and send the account to the State if you wish."

Those who insist on State attention will go to one of the 4,100, but it will not be many days before they return to their original practitioner. But if the doctors *en masse* should ever

once give any form of free treatment once the scheme comes into being, then the purpose for which we have voted and all the efforts of the B.M.A. on behalf of the profession will truly be wasted.—I am, etc.,

London, E.C.4.

C. ST. J. DE VERE SHORTT,
Barrister-at-Law.

The Plebiscite Results

SIR,—Let no one be deceived by Mr. Aleck Bourne's plea (March 6, p. 464) to overlook the results of the plebiscite. I for one would be disappointed to feel that the value of my vote and the long considerations which preceded it had been rendered void as a result of his letter. He can hardly be so optimistic as to expect his attempt to be anything but in vain. His appeal to minimize the value of its results is to be regarded as anything but a compliment to 56,000 practitioners who have given much time, thought, and worry to the whole problem. Mr. Bourne might with equal hope attempt to throw doubt on the reliability of the maternal and infant mortality rate, but in these instances he would be on surer and firmer ground by reason of his special qualification and experience. 'No! Mr. Bourne's insinuations will assuredly fall off us as water off a duck's back, and his observations can perhaps best be described in the words of Benjamin Disraeli as "a chaotic mass of heterogeneous inconsistencies."—I am, etc.,

Windsor.

PHILIP H. WILLCON.

G.M.C. to Mediate

SIR,—It is with extreme reluctance that I venture to add to the voluminous correspondence in the *Journal*, but in view of the deadlock now existing between the profession and the Government perhaps there is something in the following suggestion of an elderly practitioner (78) still in general and panel practice. It is that some use be made of the General Medical Council to bring the disputants together. We know that this body is very jealous of the standard of conduct required of all qualified medical practitioners, so why not enlarge its functions and powers to advise the Government in the present crisis as to what course should be adopted to insure the whole-hearted co-operation of the profession to make the National Medical Service a success? If there is anything in this idea of mine I must leave it to others better qualified to consider it. It would at least remove the issue out of the political arena—a very real stumbling-block.—I am, etc.,

Wymondham, Norfolk.

ALEX. P. AGNEW.

Active Resistance

SIR,—On April 1 or thereabouts we shall be receiving intimation that N.H.I. will cease and that N.H.S. will take its place on July 5. About this time or shortly afterwards we shall be invited to join the new Service and presumably to accept patients who will be treated under it when it starts. Yet as late as March 17 all the B.M.A. will have done is to offer to the Representative Body a resolution once again asking the Minister very politely whether he will not oblige the profession by reconsidering his attitude.

It has been made more than abundantly clear to most of us that the Minister will not be surprised at this and is ready for it, that he has every intention of starting his Health Service if necessary with only a "skeleton" staff, that he intends to rely on the attraction of an immediate substantial income (for it will be substantial, with so few joining) to draw in any beginners or waverers, and that he has every hope of doubling his numbers in six months and of causing a landslide within a year. I am, for one, heartily disgusted at the lack of vision in submitting a resolution of this kind so late in the day to a person who far from understanding the genuine desire to establish a good health service which lies behind it will only regard it as a sign of weakness on the part of the "old gentlemen of the B.M.A." Surely none can expect any useful purpose will be served by putting it to one whose ideas of powerful negotiation are based on strikes, lock-outs, picketing, and so forth. If all the B.M.A. propose to do at this late hour with its overwhelming majority mandate is to pursue this form of passive resistance culminating no doubt in a last-minute advice to the profession not to join the Service then we are fighting a losing battle in which we do not stand a chance. I for one, opposed as I am to the Act, do not propose to throw away the capital value of my practice in the pursuit of such a policy of futile passive resistance.

The sort of resolution I had hoped to see, not on March 17 but at least two weeks earlier, was one regretting the unaltered decision of the Minister to force his measures on the profession in spite of its clearly expressed opinion against them and stating that the B.M.A. would have now no option but to recommend immediate and forceful measures to prevent him doing so. Far from recommending that members who have accepted appointments for various committees should continue with them at present, a date in the very near future (such as a week's time) should have been set for their resignation. A token certificate strike of one week should have been prepared, with a permanent certificate strike to follow if this did not produce results. Prompt resignation from the panel on a named date (irrespective of the three months' notice necessary) should also have been provided for without waiting for intimation on April 1. Breach of contract? Of course it is! Illegal? Quite possibly. But so also are various unofficial strikes which lead the Government to appoint committees to negotiate and arbitrate. Not satisfied with this an invitation to be present at, say, Piccadilly Circus at 2.30 p.m. on some suitable weekday could be issued to the profession, and if any of us felt such a gathering beneath our dignity they might be reassured by the fact that several thousand medical students from the whole of the University of London, to say nothing of a few interested bystanders, would not.

This is the sort of argument that Labour leaders understand, and methods calculated to be effective in a dispute between, say, two faculties of a university can hardly be expected to make any impression on them. If the B.M.A. really means business it will certainly not be afraid to publish this letter. If, as Mr. Bevan thinks, it is going to give in but is only stalling, then I propose to sign on the dotted line, and I want to see action now if I am to refrain from doing so.—I am, etc.,

London, W.9.

A. LEWIS.

Confidence Between Practitioners

SIR.—The struggle for freedom in which we are engaged is a serious one, and all our resources will be necessary for success. The issue will depend on the morale of the individual doctor and on his confidence that other doctors will not accept his patients on their lists. This confidence can easily be achieved if local groups get from those general practitioners who are unwilling to undertake not to enter the Service an assurance that they will not accept other doctors' patients on their lists while the fight is on. This assurance will be given by many who will not undertake to keep out of the Service. If this action is taken by local groups all over the country our victory is inevitable.—I am, etc.,

Brookley, S.E.4.

WM. A. MACILRATH.

Enter and Improve

SIR.—The Council of the B.M.A., which should be able to speak with authority, believes that it is the whole-hearted desire of the medical profession to have a comprehensive health service available to everyone. The Acts of 1946 and 1947 are supported by all parties in Parliament, although details of these compromise measures are criticized. Our profession also must claim its right to criticize the National Health Service in its conception and operation, and to press for any alterations which it may consider desirable in the interest of the public and the profession. The present strong position of the profession results from its unity. The B.M.A. represents almost the entire profession.

We will weaken our position if we try to prevent the operation of the Acts by advising doctors not to join the Service. Such advice would not be accepted by the whole profession and would destroy our unity, which it is essential to maintain, and would appear to public opinion as an attempt to nullify the decisions of Parliament and so lose us support in our efforts to amend and improve the working of the Service.—I am, etc.,

Orpington, Kent.

L. M. FRANKLIN.

Contracting Out of Service

SIR.—It is high time we congratulated the dentists on the stand they are making against the principle of "working down to a price instead of up to a standard," as motor-car makers say. As to ourselves, the Government is trying very hard to make us general practitioners undertake a great addition to the amount of work we do under the contract system. But there is implicit in all work done on this basis a principle disadvantageous to

the sick man. The limitation and uniformity of reward tends to limitation of effort on the doctor's part and the elimination of rivalry and every other stimulus to the attainment of an increasing professional efficiency. Lost is "the spur that the clear spirit doth raise"—and more so still for the consultants. Under contract the advantage we derive is from the work we do not do. Our actual work is the burden. By convention we seldom refer to this aspect, and have schooled ourselves not even to think of it. It must have occurred to many that the possession of extra skill may turn out to be a definite drawback to its owner, carrying as it does an added responsibility. His rival who sends the case to hospital will get just the same monetary reward.

I suggest, therefore, that it is high time we made another effort on behalf of that section of the community which has in the past had our services privately. Many of these will wish to do so still, it is fair to assume, and the attempt to coerce them will give rise to a great wave of resentment as soon as they realize the implications of it. These people should be allowed to contract out of that part of the new Service which applies to the function of the G.P.s. The Government will have kept faith when it has provided the Service. That is all it "promised" to do. Compulsion is not only unreasonable but unfair. If applied at all, it should be only to those who are obviously unable to pay privately. Surely the depths of abysmal absurdity are reached when medical men are taxed in order to provide funds from which they are to be paid for doctoring not only each other but their own individual selves! We should add this contracting-out business to the list of principles on which we absolutely refuse to yield. We are under no obligation to give way on any of them. There should be no compromise. Every one of them is essential. No one will argue that it is proper to compromise on any of the time-honoured Ten Commandments, forming as they do the basis of all decent civilization.

Finally, we should not enter into any agreement with the Government until matters have been settled with the consultants. They may need our help. There is no real hurry. Another Government will carry on if this does not, and so will the healing art.—I am, etc.,

Doncaster.

W. REGINALD WILSON.

Stop Fighting

SIR.—In your issue of March 6 you publish two letters, one from Dr. Stephen Taylor (p. 463) and one from Mr. Aleck Bourne (p. 464). I wish particularly to refer to Dr. Taylor's letter. I must say that in my opinion it is a good sound letter, well expressed, and with fair, reasonable sentiments. Naturally he favours and supports Mr. Bevan, and states clearly that in his opinion Mr. Bevan really favoured the profession when the final stages of the Act were under consideration in the House of Commons. He says that but for Mr. Bevan many points which we as a profession object to would still have been embodied in the Act. I am afraid that members of the profession have looked at the Act more from a political point of view than from what is really good in a medical service.

We as a profession have stated that we favour a comprehensive medical service provided we could agree with one that suits the profession as well as the public. In my opinion we should consider what is favourable and reasonable, and acceptable to the public, and not entirely what suits ourselves. Personally I think that the good points in the Act outweigh the "prickly points" which we allow to prick us. We ought to endeavour to come to an agreeable settlement, which ought to and will benefit the doctors and also those who are placed in our care. Surely the little points which we object to can be rectified. The higher qualities of man—namely, his intellect and his reason—should have predominant consideration rather than his lower ones, such as "fight" and "force." I believe that if we abandon these terms, so freely used in all our controversies, we shall succeed; for as Dr. Taylor states, referring to Mr. Bevan, "In any reasonable attempt to find a solution and make a success of the Health Service, he will play fair; in battle, he will neither give nor ask for quarter." Let us therefore act upon our intellect and reason and abandon the spirit of fight and power, otherwise in the long run I am afraid we stand to lose.

I sincerely hope that a solution on these lines will be arrived at, and that a good medical service can be formulated and carried out in practice. The profession have asked for it for the past thirty years, and the public are clamouring for it, and naturally it is difficult to come to an agreement on all points favourable to us, and we must be prepared to give and take. Attempts have been made by former Ministers of Health and nothing has come of their efforts. I refer to Mr. Ernest Brown and Mr. Willink. In the present Act there is much that we can consider more favourable to us than unfavourable, and by reason we can and ought to eliminate those things which prick us. We have in our leaders all those accomplishments which are necessary, provided only that we drop the spirit of fighting and gaining victory. I do hope and pray that this will be so.—I am, etc.,

Cardiff.

ARTHUR T. JONES.

Spectator in Eire

SIR,—May I as an interested spectator claim the honour of congratulating the B.M.A. on its gallant stand? It is heartening to us who may presently face the same set-up here to witness your all-out mobilization against this threat to submerge the profession in the State almighty.

If shackling the freedom of the doctor is justifiable on the grounds that he is a key man in the modern State, then what of the shopkeepers? Food, clothing, shelter are the basic needs of the citizen; after these comes medicine, but well down the list. If it is imperative to harness the doctor to the State machine it follows that all those who serve more essential needs must be roped in—namely, the grocer, the butcher, the baker, the draper, *et hoc genus omne*. This is but a logical extension of the new Health Bill. Hence the grocer must be salaried or put on a limited income, must open his shop where directed, be liable to dismissal without protection of the law courts, give up goodwill in his business as immoral, and in general renounce all freedom of human enterprise.

The average citizen sees nothing in this fight but a squabble between the Minister and the doctors about selfish interests. Many who are now complacent would think seriously if they realized that the doctor fights a menace to-day that will threaten them to-morrow. Our democracy is slipping. The continual shift to the left can end only in the Russian quality of democracy, that sombre way of life whereby man's honour and freedom on earth perish utterly.—I am, etc.,

Galway.

C. CONOR O'MALLEY.

Basic Salary

SIR,—The one and only thing the whole profession appear to be united about is their fear of being converted into salaried State servants. Their dislike of basic salary arises chiefly from this fear. Surely, therefore, this is the main point to be settled, and it could be easily settled by the insertion into the Act of a clause making the basic salary permanent at £300, unless by the mutual consent of the Minister and the profession. Apart from this fear, judging from former expressions of opinion, there does not appear to be any deep dislike of the basic salary as such. Once this objection is settled the other points appear capable of settlement on similar lines. It is as well to realize that when this matter is settled it will probably be settled by compromise. It is up to the Minister to invite the B.M.A. to consult with him with a view to settling this dispute as quickly as possible.—I am, etc.,

Paignton, S. Devon.

P. M. GARRY.

Whole-time Medical Officers

SIR,—I am very sorry to note from your leader (Feb. 28, p. 397) that you apparently approve of the objectionable references to whole-time medical officers in Prof. Dible's recent letter to *The Times*. If the B.M.A. has a good case against the N.H.S. Act it will not be improved by gratuitous attacks on a not unimportant branch of the profession. To say, as Prof. Dible does, that whole-time medical officers have, above all their other alleged deficiencies, no zeal is in my opinion an unnecessary insult and in my experience untrue.

I should have thought that at this time at any rate Prof. Dible would have preferred to encourage a united professional front.

He should not bolster up his case by belittling a body of men whose choice of work may not be his own but who nevertheless are carrying out their duty to their patients conscientiously and to the best of their ability. Whole-time service does not of itself necessarily mean a lack of professional enthusiasm. I challenge Prof. Dible to tell me where there is a more zealous body of medical men and women than are to-day to be found in the whole-time municipal hospital service of this and many another city.—I am, etc.,

Leicester.

E. K. MACDONALD.

Plums and Patronage

SIR,—Taunts have been thrust at the B.M.A. for presuming to recommend the continuance of the sale and purchase of practices. Doctors have been called mercenary dealers in bodies and souls. Why the doctor, who dispenses medicines, should be so stigmatized any more than the grocer, who dispenses food, is difficult to understand. In each case the purchaser considers an expenditure that places him in the position of making a livelihood worth while. In neither case is compulsion brought to bear upon the clients to continue their patronage except in the matter of availability, which would apply equally were no payment for goodwill made. In both cases the situation has arisen by evolution in response to the law of supply and demand. It brings reward to the man who has been industrious, and checks exploitation of such industry by those who want to get something for nothing. Should remuneration in the Health Service be by capitation fee, the purchase and sale of practices could continue as before and provide the same safeguards.

Quite apart from what it would have saved me at the beginning of my career I entertained the feeling that their abolition was desirable, in that it would place the doctor on a higher ethical level than the business man in this matter, as already does the way the doctor handles his discoveries, which he does not patent but gives freely to the world. Second thoughts indicate that this feeling is idealistic rather than expedient. Even in the Health Service some of the practices that come to be relinquished will be plums compared to others. If they are going without money and without price, who is to get the plums? One can see the ropes being pulled in the allocation committees with various members working for their own protégés. As the committees can be filled almost entirely by the Minister, the plums would fall most naturally to the good Socialist or good Conservative, depending upon what Government happened to be in power. An opening would also be made for the unscrupulous receiving backhanders as *purchase price* for their votes and influence in favour of certain candidates, a practice not uncommon in other walks of life.

The continuance of sale and purchase, though it may have drawbacks, would seem to be less likely to stir up human resentments and more conducive to fair dealing than a situation which exposes the disposal of practices to the vagaries of the unscrupulous and the whims of political patronage.—I am, etc.,

Glasgow, S.3.

W. MELVILLE CHRISTIE.

Public Opinion

SIR,—It is a heartening sight to see the members of the depressed or sweeper class of the profession at last moved to protest, and as a newly enrolled member of the League of Doctors' Wives may I put forward a fresh point?

You are no doubt aware that the general public is not, unfortunately, 100% behind the doctors in their opposition to the Act in its present form. As a professional lecturer I am bound to say I am not surprised, as the B.M.A.'s "publicity" has been to say the least, confusing to the layman, and emphasis has been laid on the wrong points. The public does not care a Shinwell's cuss how a doctor is paid, or whether he is paid, and the word "buying and selling of practices" have loomed too large in the newspapers. The impression has grown that this is a financial squabble, and the public has suffered a rude shock to its idealism for a doctor, as they well know, is a dedicated being with no interest save the fight against disease, and with a soul above such sordid details as remuneration. Nobody likes an idol to have feet of clay, and the Minister of Health is a sufficiently clever strategist to take full advantage of his public sense of disillusion.

LIVER *at meal times*

In a Palatable, Readily Acceptable Form.

Proteolysed Liver A & H is prepared by a process which eliminates the nauseating flavour of raw liver. Its palatability has been further improved by its presentation in a paste form. It may be readily incorporated in the normal diet by its inclusion in soups or as a sandwich spread.

In pernicious anæmia and other megalocytic anæmias, proteolysed liver has proved effective in cases which have failed to respond to extracts of liver in general use.

INTRODUCING—

Spascol

THERAPY OF

SPASMS and of DYSMENORRHOEA

Containing an important new synthetic anti-spasmodic compound, offering outstanding advantages over papaverine in the symptomatic treatment of spasms and dysmenorrhoea.

1. RAPID AND PROLONGED THERAPEUTIC ACTION. (1 tablet taken orally gives prompt relief, lasting from 3 to 6 hours).
2. NON-HABIT FORMING.
3. WELL TOLERATED.
4. EFFECT IS MAINTAINED BY A SMALL DOSE.

Samples and Literature on request

FORMULA: Each tablet contains

1—(3:4:5, triethoxyphenyl)—6,7— dimethoxyisoquinoline—	0.04 gm.
Hyosine Hydrobromide—	0.0001 gm.
Ext. Belladonna—	0.001 gm.
Rubiacina, Rhel—	0.005 gm.

To help vanquish depression associated with persistent pain

Many patients suffering from persistent pain are subject to attacks of depression characterized by deep apathy and emotional exhaustion. Thus, pre-existing neurotic tendencies may be exaggerated and the pain threshold progressively lowered. By restoring morale and optimism, 'Benzedrine' Tablets will often effectively combat the depression which may complicate the management of painful conditions.

Response to 3
Fersolate Tablets
daily: a case of
quite severe iron
deficiency in a
woman aged 43.

the most **positive** treatment for the most **common** deficiency

Anaemia caused by lack of iron is seen in day to day practice more often than any other condition due to nutritional defect. Iron in the most effective form—ferrous iron—provides the rational, straightforward treatment. Fersolate, the tablet preparation of ferrous sulphate with traces of copper and manganese, is widely used for combating the iron deficiency anaemias. Haemoglobin regeneration occurs at a daily rate of one to two per cent—usually from a dose of 3 Fersolate Tablets per day—and the patient's well-being is rapidly restored.

GLAXO

FERSOLATE TABLETS

Each tablet contains exsiccated ferrous sulphate, 200 mg ;
copper sulphate, 2.5 mg. ; manganese sulphate, 2.5 mg.

SPIRELLA HOUSE, OXFORD CIRCUS,
LONDON, W.1.

On the other hand, the public is very much interested in the rights of a citizen, and in my humble and diffident opinion much more emphasis should have been laid on this aspect of the Act. For example, the notorious paragraph 42, which provides the tribunal for the dismissal of "any person . . . whose continued inclusion would be prejudicial to the efficiency of the service . . ." No mention is made in this paragraph of professional efficiency or otherwise, and in its present form it provides an extremely handy weapon for political or racial tyranny of the worst order.

Is it too late for the publicity of the B.M.A. to take a slightly different line? One cannot expect doctors to know all the tricks of advertising agents, nor would one wish it; but in the present situation the full support of the public would make all the difference between certainty of success and the possibility (almost unthinkable) of being obliged to yield to financial blackmail.

Incidentally I have just returned from a lecture tour in which I spoke at the Education Offices in Ipswich. A large board in the main hall was attractively set out with anti-B.M.A. propaganda. The letterpress ended with a jubilant paragraph to the effect that doctors would be obliged to yield for financial reasons.—I am, etc.,

Scarborough.

GWENDOLINE BAKER.

Branch Managers

SIR,—So now the doctors' wives are up in arms. Rightly so. Why should they be caretakers and dustwomen for businesses that's all they will be) belonging to the State? The doctors in Northern Ireland (though some don't know it) will cease to own their practices on and after July 5. Are these doctors going to accept service as branch managers for a multiple concern and work 24 hours daily? No other employees are asked to do it. Should we? Certainly not.—We are, etc.,

E. J. A. DOUGAN.
H. P. LOWE.

Passage of Vitamin E to the Human Foetus

SIR,—In the annotation (Feb. 28, p. 400) on the passage of vitamin E to the human foetus you make the following statement (now repeated so often that I suspect its elimination from textbooks will not become possible for two generations even should it be proved incorrect): "Evidence that it is required by human beings is still inconclusive. It has repeatedly been claimed that vitamin E is of use in the treatment of habitual abortion, but sceptics have pointed out that abortions are often followed by full-term gestation even without special treatment."

In support of these statements you give a reference to some publications between 1933 and 1939. Surprisingly enough you make no reference at all to a more recent publication in which precisely this point was considered. In 1940 I summarized all the published records about the treatment of habitual abortion with vitamin E and compared, on certain assumptions which I hope were clearly stated in the paper, those figures with the expectation of full-term delivery in a habitual abortant, as shown by Malpas's previously published figures. The conclusion reached was that there was an overwhelming probability against the successful gestation in the treated patients being due to chance and not to the vitamin-E therapy.

My arguments may or may not have been sound; to the best of my knowledge they have not been criticized in the intervening eight years. Had a valid criticism been sent to you, Sir, it would presumably have been published for reasons identical with those that led you to publish my own contribution to which I have just referred (*British Medical Journal*, 1940, 1, 890).—I am, etc.,

Greenford, Middlesex.

A. L. BACHARACH.

The Posterior Pituitary and Labour

SIR,—Dr. G. W. Harris has summarized (Feb. 21, p. 339) the evidence relating to the theory that the posterior pituitary contributes to the processes of labour. I would like to record an observation which suggests that a discharge of pituitrin-like substance occurs with each uterine contraction of labour. In 1941 a woman who had borne one child and fed him until recently from the breast was in labour with her second child.

She happened to develop a measles rash at the same time. While the rash was being looked at, beads of milk were seen to stand out on the nipples with each uterine contraction, as they do from a lactating breast during the "draught" (a process corresponding to the letting-down of milk in cows) or after injection of pituitrin. Since the "draught" is believed to be due to secretion from the posterior pituitary, the expulsion of the drops of milk was taken as evidence that a similar secretion was occurring with, or was preceding, each uterine contraction. An injection of pituitrin at the conclusion of the second stage in this case caused the expulsion of more drops of milk.

The fact that this visible expulsion of milk during labour is exceptional—and I have not seen it since—is perhaps because the breasts rarely contain enough free-flowing secretion at term. Its rarity does not therefore necessarily rule out the tempting conclusion that labour proceeds from a series of discharges of pituitrin-like substance which acts on the prepared uterus and which is rapidly rendered inactive.

If there is indeed a fresh discharge from the pituitary evoking each contraction it is curious that an injection of commercial pituitrin given during the first stage alters the whole course of labour. Possibly the extracted active substance is more stable than the form secreted physiologically, or the crescendo of labour is produced by some cumulative action.—I am, etc.,

Essex, Surrey

MAVIS GUNTHER.

Rectal and Vaginal Temperature

SIR,—May I offer some remarks in reply to the criticisms levelled against the use of the rectal temperature readings in the study of ovarian activity? During the past five years I have been using temperature readings whenever possible in thousands of cycles; some of the findings were published some time ago (*Lancet*, 1945, 2, 663). This procedure was chosen after extensive trials for several reasons.

1. Whereas it may be easier to persuade some types of patients to take an oral reading, there are an equal number who prefer to take a rectal reading as they are afraid of breaking the thermometer on the teeth. This particularly applies to hospital patients pressed to employing thermometers.

2. Mouth-breathing at night, and even for a short time on waking, does lower the temperature and obscures the pattern of the temperature cycle in some women. This is not compensated, as suggested by Miss Joy L. James (Feb. 21, p. 368), by closing the mouth for five minutes before taking the reading, since this precaution delays the recording and may thereby involve a misleading reading through a rise from waking level.

3. The absolute level of the temperature is of importance, for it reflects the endocrine activity of the ovary, a matter of clinical importance quite apart from the biphasic nature of the curve.

If records by different workers are to be compared, it is essential that the discrepancies introduced by the different procedures and by the variable individual difference between rectal and oral readings should be eliminated.—I am, etc.,

London, W.1

MARY BARTON.

Scepisis Scientifica

SIR,—It seems to me that Prof. Geoffrey Jefferson, in his lecture "Scepisis Scientifica" (Feb. 28, p. 379), avoids the main problem in modern medicine, which is by what means and in what manner do we temper scientific thought with scepticism and at the same time avoid the paralysis of science by a completely pragmatist attitude. That the predominant influences in present-day medicine are crude forms of empiricism, relativism, and pragmatism there can be no doubt. Scepticism has by a one-sided and false development become elevated to the role of a scientific religion. It is useful to examine the historical origins of this situation and to attempt to reveal how this "hypertrophied" development of scepticism does in fact operate as a paralysing influence in medicine.

Woodger, in his inexplicably and unwisely neglected work *Biological Principles*, demonstrates that the main philosophy influencing biology as a whole is that of the so-called phenomenologists, Mach, Avenarius, Pretzoldt, Karl Pearson, etc., who have revived and extended the subjective-idealist scepticism of Bacon, Locke, Hobbes, and Hume. The phenomenologists argued that as our knowledge is only relatively true, since those things which are "true" to-day are no longer true to-morrow, and as our

imperfect senses are incapable of accurately reflecting objective reality; so we are excluded from the possibility of any real knowledge.

For such a philosophical standpoint carried to its logical conclusion, truth and untruth, objective fact and illusion, scientific knowledge and primitive superstition, are all equally valid, and the scientist accepting these views is automatically led to empiricism and pragmatism. With Dewey, he is forced to believe that knowledge is an instrument which depends on our interests and advantages, and he eventually develops a completely cynical approach to his subject. It is especially the great complexity, the enormous number of mutually interconnected processes in living matter, together with the comparative lack of success of medical investigation when superficially compared with the so-called exact sciences—physics, chemistry, and mathematics—which make the medical worker particularly liable to adopt such an attitude.

Thus there has arisen in biology on the one hand a neo-vitalism which claims that the living organism is "unknowable" and that all we can do is lead a despairing "hand-to-mouth" existence of accumulating more and more facts in a strictly empirical manner. On the other hand, the superficial appearance of exactness and logic of the physical sciences has stimulated some medical men to "impose" on medicine the principles and methodology of these sciences, in the mistaken impression, which Prof. Jefferson appears to share, that "the only sciences which have succeeded in producing immediate conviction and durable results are mathematics and those in which mathematics enters to a very great degree." The latter medical workers (among whom we cannot include Prof. Jefferson, in my opinion one of the truly great figures of contemporary medicine) seek to explain biological phenomena as mere extrapolations of physico-chemical phenomena, and mechanically attempt to reduce biology to physical, chemical, and mathematical terms. Thus we constantly see, for example, medical workers attempting to obtain from statistical assessments information which such procedures are incapable of producing. They forget that from statistics we are unable, by means of them alone, to come to any other than purely quantitative conclusions; that for conclusions which involve qualities other additional methods of investigation and reason are necessary. Unfortunately we have not sufficient space to illustrate further the exact manner in which the philosophical conceptions described above operate in present-day medicine, but we may profitably examine the epistemological basis of these conceptions.

Views such as those held by the phenomenologists and the pragmatists have as their basis the isolation and exaggeration of but one aspect of human knowledge—the fact that it is "limited. Knowledge is limited and relative because it is an endless approximation to external reality," and because every theory depends on the limits set by the historical experience of social practice. Knowledge advances in a contradictory manner, but scientific experience, handed down from one generation to another, is each time enriched by new scientific discoveries and is all the time increasing the possibility of adequate knowledge of objective reality. By exaggerating and isolating one aspect of knowledge—its limitations, its relativity—the phenomenologists and pragmatists distort it and produce a sterile and despairing empiricism.

In fact, biological phenomena, sociological principles, etc., are no less real and "exact" because they cannot be expressed in terms of physics or mathematics. Biology, however, has considerably lagged behind the development of the latter sciences because, by reason of its subservience to outmoded philosophical systems, it has remained in the stage of the empirical collection of facts, a stage which physics, for example, has long since outstripped. All sciences proceed through this empirical stage in their development, but in order to make further advances they have also to construct fundamental principles, generalizations derived from the facts, which give to the science an operable theoretical basis. As Walshe has said, the season of synthesis of the innumerable available facts of medicine is long overdue, and one may add to this that this season will not appear until medicine rids itself of scientific pragmatism.

One last point: I strongly disagree with Prof. Jefferson's comparison between that giant of philosophy, Bacon, and Wilfred Trotter. The latter, whose philosophical stature has in my opinion been greatly exaggerated by medical men, has not written anything of which I am aware which can be compared either in originality of thought, lucidity of exposition, or logical development with Bacon's philosophical works. His eminence as a medical philosopher is mainly derived from "the flatness of the surrounding country."—I am, etc.,

London, S.W.3.

A. McPHERSON.

Pyopericardium

SIR.—Lieut.-Col. A. L. Wingfield (March 6, p. 451) concludes his interesting report of a case of pyopericardium treated with apparent success by aspiration and penicillin instillation by saying: "The final outcome remains conjectural, but eventual pericardial symphysis appears inevitable, although there are no signs of it at present."

This statement helps to perpetuate the great confusion of thought concerning chronic pericardial disease, for although it must be agreed that diffuse adherence (symplysis) between the two layers of serous pericardium is probably an inevitable sequel to recovery from a pyopericardium, such adhesions do not produce symptoms or signs during life.

I think it is probable that the author means that there are no signs of chronic constrictive pericarditis (Pick's syndrome), which is the best definition employed to describe thickening and loss of elasticity of the pericardium with consequent limitation of diastolic filling of the heart (chronic cardiac tamponade). Tuberculous infection, usually healed, is thought to be the most common cause of this syndrome, but there may well be a risk of its occurrence following suppurative pericarditis treated successfully by penicillin without drainage, although so far as I know it has not yet been reported. Further experience should decide this point: meanwhile it would appear unwise to dogmatize on the future of the operation of pericardiectomy.

"Adherent pericardium" is still used indiscriminately to describe (1) simple adhesions between the pericardial layers which do not cause symptoms or signs, (2) chronic constrictive pericarditis which causes chronic cardiac tamponade, and (3) mediastino-pericarditis (adhesions between the pericardium and the chest wall) which is supposed to cause massive enlargement of the heart but is probably not an entity at all.

It isn't fair on the student.—I am, etc.,

London, W.1.

OSWALD S. TUBBS.

The Colonial Medical Service in Aden

SIR.—Of late much attention has been focused on health services. Having very recently returned from Aden, where we served in the R.A.F.V.R., we consider that a little open criticism of the backward conditions under which the Colonial Medical Service has to work in that colony should be laid before your readers. We do not desire that this should be interpreted as a deterrent to any doctors intending to join that service, but rather that it should stimulate rapid action in the matter of improvement or at the very least acquaint your readers with undoubted facts with which the Colonial Office cannot but be acquainted.

For a period of approximately six months we acted as surgeon and anaesthetist respectively at the Civil Hospital in Aden when that hospital possessed neither; and for the whole of our tour in Aden we were associated in many ways with the Colonial organization from our respective positions as officers in charge of the surgical and medical divisions at the R.A.F. Hospital. Let it be stated here that we do not gainsay our fortune in being allowed such access to medicine nor the friendly and co-operative way in which we were treated by all the staff at the Civil Hospital, who, working under dreadful conditions with difficult patients, did sterling work. We merely criticize existing inadequacies.

The population of Aden is in the neighbourhood of 80,000, a great increase having taken place during the recent war. Hospital accommodation was hopelessly small—so much so that even the acceptance of only emergencies necessitated patients being on the floor between beds. The existing "wards" were outdated, unequipped, and impossible to keep clean; one lavatory basin sufficed for roughly 70 patients. Lack of accommodation, inadequacies of design, and out-of-date equipment meant that even with the best will in the world the overworked staff could not keep the place or the patients clean. Dirt and flies abounded—the latter despite the fact that in other parts of Aden with similar surrounds flies were considerably less common than in this country. There were no out-patient departments worthy of the name, and the majority of surgical out-patients were seen outside and dealt with as well as such a situation permitted. When it was necessary to examine them more thoroughly they had to be laid on the operating table in the minor theatre, dirt and all. Patients waited in the sun. The main operating theatre was just adequate in size, but it was not until a strong letter was written by one of us that air-conditioning was instituted. Previously two fans over the table circulated the air, while an open window overlooking the dirty active town acted as a ventilator.

Equipment was limited, and essentials such as scalpel blades and rubber gloves were often missing and had to be borrowed from the R.A.F. It is reliably reported that a certain surgeon on one occasion had to use scissors to make his skin incision for an abdominal operation. There was no anaesthetic machine. For head-and-neck surgery a Heath-Robinson arrangement of borrowed equipment was used. A catheter was attached to rubber tubing and this in turn to a funnel. On to a piece of gauze wrapped over the funnel the ether was dripped. There was no alternative. There were no adequate resuscitative measures available except from R.A.F. sources. If we needed saline, plasma, or blood we had to supply them and the transfusion set. The local saline was so pyrogenic that it was unusable. Oxygen cylinders were supplied, but as there were no workable masks they were of limited value. Sterilization of all dressings was carried out by the R.A.F.

Ancillary medical services were elementary. A workable x-ray unit was only fitted some weeks before we left. Pathological services were limited to the most simple investigations, and more complicated procedures were carried out by the R.A.F. Practically all the public-health aspect of the work was done by the R.A.F. laboratory.

The control of endogenous diseases, considering the primitive sewage system and appalling housing conditions, appeared to be of little avail. Amoebiasis, for example, was widespread and tuberculosis common. Owing to the very limited accommodation available only a small number of cases of the latter disease likely to respond to conservative treatment were hospitalized. Advanced cases spread the disease.

We have made no attempt to list all the inadequacies—space does not permit—and while appreciating that some good has been done by the Colonial Medical Service in Aden nevertheless the general impression created is more than disappointing. Plans, we believe, have been prepared for some time for building a new hospital, but it should be obvious that many defections are unconnected with buildings. In concluding it is worth remembering that Aden is a "shop window" for Great Britain, and that a great many nationalities pass through the port. We felt that no poorer advertisement than the existing medical arrangements could be offered.—We are, etc.,

Pulmonary Embolism

SIR,—I welcome Mr. Reginald S. Murley's criticism (Feb. 28, p. 415) of my article "The Aftermath of Gastrectomy," which was of course no more than a brief summary of a huge subject. Even so I should have devoted more than six lines to an aftermath as serious as pulmonary embolism. However, I am not totally ignorant of modern views on the subject regarding the importance of deep peripheral thrombosis. When Mr. Murley says that my statement, "Thrombosis usually arises in the abdominal wall, or, as in two of these cases, from extension of the thrombosis of haemorrhoids . . ." is preposterous, I disclaim all responsibility and place it fairly and squarely on the shoulders of Nature, since these cases were proved by post-mortem examinations which I personally witnessed—the clots being traced respectively into the azygos and iliac veins (in one a mass of clot still projected into the superior vena cava from the vena azygos major). Nature has an awkward habit of being "preposterous" and oft-times interferes most inconsiderately with our ideas.

I should like to add that as a house-surgeon I was brought up to believe in the value of post-operative leg massage and exercises, introduced in those far-off days by Rutherford Morison, and this practice has been followed throughout my surgical life. However, as the figures in my article reveal, I have not been able to avoid pulmonary embolism by such simple measures. The modern extension of this idea and the introduction of reliable anticoagulants will it is hoped reduce the incidence of this dire complication, but I think I was right in saying that it still remains "a bugbear," which the O.E.D. gives as "an object of (needless) dread."—I am, etc.,

NORMAN C. LAKE.

London, W.1.

Bone Conduction in Otosclerosis

SIR,—The report in the *Journal* of Feb. 14 (p. 308) of a paper on bone conduction in otosclerosis, read by Dr. R. R. Woods at a meeting of the Section of Laryngology and Otology of the Royal Academy of Medicine in Ireland, focuses attention on the gain in bone conduction in the operated ear which occurs after the fenestration operation for otosclerosis.

In this connexion I would like to emphasize the considerable lengthening of bone conduction which may occur in the unoperated ear after a fenestration operation on the other ear. This lengthening of bone conduction is a matter of clinical importance, as the following case illustrates.

A man aged 47 consulted me for bilateral deafness getting steadily worse during the last three years. He complained of moderate buzzing noise in each ear. On testing the hearing of the right ear, conversational voice could not be heard distinctly at a distance greater than one-and-a-half feet; with the left ear loud conversation could only be heard occasionally at about one inch. On testing bone conduction with a 256 tuning fork it was found to be lengthened by a few seconds on the right mastoid bone and to be reduced by about 50% on the left mastoid bone. The ear drums were normal in appearance and the eustachian tubes were freely patent.

As a result of the reduced bone conduction in the left ear it was thought that there was likely to be a considerable degree of nerve deafness in this ear. On the other hand, the findings with the right ear indicated that a good result to the fenestration operation on this ear was likely. A right fenestration operation was therefore performed. During the second week after this operation the hearing to conversational voice with the right ear improved to hearing at a distance of about twenty feet. At the same time hearing to conversational voice with the left ear improved to about one foot, and bone conduction, using the same 256 tuning fork, was lengthened to normal for this fork.

In view of the improved bone conduction in the left ear it was decided to do a second fenestration operation on this ear. As there was very little giddiness this was done three-and-a-half weeks after the first operation. The patient began getting up four days after the second operation, as there was even less giddiness after this operation than after the first operation. During the second week after the operation the hearing with the left ear became as good as the hearing with the right ear.

The patient was discharged from hospital six weeks after the first operation, and was back on duty as a commercial traveller two weeks later. It is now six weeks since he left hospital, and all tinnitus has subsided and he is hearing conversational voice at about twenty-four feet in each ear.

The lengthening of bone conduction described above is one manifestation of a syndrome which I call contralateral concomitant auditory facilitation of the fenestration operation. Usually in the less marked cases of bilateral deafness the syndrome is marked by considerable improvement in hearing to conversational voice by the unoperated ear.—I am, etc.,

London, W.1.

W. H. B. MAGUIRE, M.D.

Calciferol in Tuberculosis

SIR,—Under dispensary conditions my experience with calciferol in tuberculous cervical adenitis has not been so satisfactory as that obtained by Dr. G. B. Dowling *et al.* (March 6, p. 430) treating cases in institutions. Over a period of four months seven out of eight cases given 100,000 units of calciferol daily by mouth showed a slow improvement which could easily have been due to the other general measures employed. In one case the glands broke down and operation for an abscess was required.

From this it would appear that once a case is under suitable conditions calciferol acts by giving a stimulus to the defence mechanism of the body. Such an action has been noted in six cases of advanced pulmonary tuberculosis. Three or four weekly intramuscular injections of 300,000 units of calciferol improved the general condition, reduced the degree of fever, and induced a gain in weight. No adverse toxic effects were seen in treating these cases of pulmonary tuberculosis.

One other case received 6,000,000 units by injection in 26 days. There were no deleterious effects, nor was any improvement noticed.—I am, etc.,

Walsley

R. GREENVILLE MATTHEWS.

Retroperitoneal Haemorrhage in Pregnancy

SIR,—Dr. J. Kenworthy Ogden's report of this case (Feb. 28, p. 389) is of great interest. It does not appear necessary to try to correlate the aetiology of retroperitoneal haematoma with toxæmia of pregnancy. The post-mortem findings confirm the presence of massive spontaneous intraperitoneal haemorrhage with no definite bleeding point. The first reported case of this condition was by Barber in 1909. The patient, aged 32 collapsed two days after labour. At operation no definite

bleeding point was found. She recovered. There was no mention of toxæmia of pregnancy in this case.

In the absence of high blood pressure and arteriosclerosis the heart is incapable of raising the blood pressure sufficiently high to cause rupture of a normal artery, and some congenital or developmental defect must precede spontaneous rupture. Bruce (1937) suggested that the hæmorrhage in this group may be due to rupture of a miliary aneurysm or a "junctional area." Bruce's suggestion was soon confirmed by Schuster (1937), who described a case of multiple aneurysms of the splenic artery which she believed were of congenital or developmental origin in a case of familial hæmorrhage telangiectasis. Shallow, Herbut, and Wagner (1946) demonstrated defects in the muscle coat of the inferior pancreaticoduodenal artery associated with a ruptured congenital sacular aneurysm at the first bifurcation and three small fusiform dilatations in the more distal parts.

At post mortem it is often difficult to demonstrate the bleeding point in this type of massive spontaneous intraperitoneal hæmorrhage. However, careful dissection of the affected part and sectioning of the neighbouring vessel will demonstrate the cause—a ruptured miliary aneurysm or congenital defect of the arterial wall.—We are, etc.,

Liverpool.

Cancer of the Lung

SIR,—With reference to recent correspondence I wish to draw your attention to the fact that in a small research (confined to males) carried out here it was found that the incidence of cancer of the lung fell more heavily on smokers than non-smokers—correction for age having been made. Unfortunately the number of cases investigated was too small to be statistically significant.

Our ignorance of the fundamental cause or causes of cancer is almost completely unrelieved. We know that in a small proportion of cases the inciting cause is the repeated application of a carcinogenic agent contained in tar, soot, oil, or other substance. The apparent increase in cancer has been almost entirely in cancers of inaccessible parts of the body.

Improved methods of diagnosis—of which radiology is the chief—are accountable in part for the greater frequency with which a diagnosis of cancer of the lung is now made. Also it is possible that more people develop cancer of the lung because more people live to the age at which cancer usually occurs. Gassing during the first world war and its sequelae apparently did not predispose to lung cancer.

Whether tars or other agents contained in tobacco act as carcinogenic agents in the lung is a disputed question. A complete statistical survey of smokers and non-smokers on this point has yet to be made. The quality and amount of tobacco consumed, the frequency of inhalation, age, sex, race, and all other relevant factors would have to be included in such an investigation.—I am, etc.,

Public Health Department, Halifax.

G. C. F. ROE.

Intervertebral Disk Lesions

SIR,—Dr. Michael Kelly (Feb. 28, p. 416) rightly draws attention to the well-known observation that pain is not a characteristic feature of lesions known to produce pressure on nerve trunks. As was shown by Lewis and Pochin,¹ in nerve paralysis from pressure touch fails early, motor power next, "fast" pain later, and delayed pain last. Before pain sensation is lost transitory hyperalgesia may occur, so that the earliest signs of nerve pressure are alternating periods of numbness and cutaneous tingling in the area of distribution. Pain such as that of the sciatic syndrome does not occur.

On page 424 of the same issue, however, your adviser's reply under "Any Questions?" follows traditional thought in suggesting that the sciatic pain of disk lesions is due to pressure or stretching of nerve-roots. That may be so, but there is at least some evidence that other factors are involved. Kellgren and Lewis² demonstrated that irritation of a deep somatic structure such as an interspinous ligament by injection of hypertonic

saline resulted in pain throughout the corresponding sclerotome with accompanying muscle spasm. We can aver from personal experience and self-experiment that the pain produced by so stimulating the fifth lumbar interspinous ligament is clinically and subjectively indistinguishable from that occurring spontaneously in an L5-S1 disk lesion.

Now, primarily, herniation of the nucleus pulposus is a joint lesion which produces strains on surrounding ligamentous structures and may finally give rise to nerve-root or spinal compression. Such a joint disorder might reasonably be expected to produce pain throughout the corresponding sclerotome, irrespective of whether or not nerve pressure occurs. In fact, a large proportion of patients in whom the diagnosis is subsequently confirmed by operation never present any acceptable objective evidence of nerve pressure such as muscle weakness, anaesthesia, or loss of deep reflexes.

Before the phenomena are clearly understood two facts must be explained. (1) Application of a short plaster corset, even without preliminary extension, may rapidly relieve pain, although the area of anaesthesia persists or, as in one case under our observation, actually increases. Clearly such benefit cannot be due to relief from nerve pressure, but it may well be the result of immobilizing, at least partly, the grossly deranged spinal joint and thereby diminishing the deep segmental pain arising therefrom. (2) We have found that in many cases of undoubted disk prolapse temporary relief from pain follows injection of the corresponding interspinous ligament with 1% procaine solution. This cannot be the result of relief from nerve pressure though the change may be explicable upon the basis of the theory recently propounded by Cohen.³

The understanding of the pain mechanisms involved in these cases is a matter of some importance. In most instances the primary necessity of treatment is the relief from pain, a problem as yet incompletely solved. Fuller understanding of the manner in which pain is produced will surely pave the way to more universally satisfactory results.

It is generally accepted that on clinical evidence alone the level of a lumbar spine disk lesion cannot be confidently predicted. It may be that the present conception of sciatic pain as the result of root compression is responsible for this difficulty, and if it were regarded as a deep segmental pain due to joint disturbance this difficulty might be resolved. Over-simplified views of the pain mechanism in this condition are liable to follow a mechanical interpretation of the functions of the central nervous system.

The problem is a complex one and, clearly, many questions remain to be answered. We are at present engaged in an investigation of this subject and hope to communicate our findings in due course.—We are, etc.,

The Extent of Neurosis

SIR,—Stimulated by the correspondence on this subject I decided to classify the patients I saw during a period of twelve weeks—from Nov. 9, 1947, to Jan. 31, 1948. Some of the facts and figures emerging may be of interest. The practice under review is a large mixed-private and panel practice in a town of some 25,000 inhabitants, extending also to some of the neighbouring villages. It is run by four partners, who share the work as equally as possible, apart from the fact that nearly all the anaesthetics are done by one partner, and a very large proportion of the midwifery by another. This accounts for the rather disproportionately small showing of these two types of work in the figures following, since the work is that of one partner out of the four.

A total of 3,200 patients were seen; of these 1,744 were surgery attendances, 1,074 were visits to patients in their own homes, and 382 to patients in the local cottage hospital. 2,241 were "old patients," while 959 were first attendances.

Among the acts of service were included: minor surgery, 43; injections, 82; anaesthetics, 3; obstetric attendances, 43 (including 16 antenatal and 4 post-natal examinations); life insurance, 6; examination for entrance to Civil Service, etc., 10.

Not included in the total of acts of service above was the dispensing of medicine on 656 occasions and the making of 50 telephone calls on behalf of patients. Furthermore, the paper work in the course of this period, apart from record-keeping, included the writing of 1,034 prescriptions and the issuing of 879 certificates of various kinds, as well as the notifying of 21 cases of infectious

concerning the developing attitude to the external world, to the body, and to the inner world of phantasy, memory, constructive thought, and so forth; and further work in this field should lead to our understanding of much that we are ignorant of in the psychopathology of schizophrenia.

Love and Hate

But it is the next step in development to which I wish to refer specifically. Sooner or later *sufficient integration occurs for the infant to realize that the memories of the loving satisfying breast and the hated frustrating breast are of one and the same breast, and that memories of the happy, sucking mouth and of the angry, frustrated, hungry mouth are of the same mouth.* I said "sooner or later"—the time will depend at least on the degree of maturity at birth, the constitutional intellectual endowment, and the quality of the previous emotional development. In other words an integration seems to occur in which the belief in a continuing self, or what would later be called a part of the self, emerges and the belief in continuing people in the environment, or what would later be called parts of these people, emerges. Coincident with this integration a new affective state arises. The realization that maximal love and maximal hate can be expressed by the same bodily organs, that both maximal love and maximal hate can be felt towards the same object, and that this object can be both satisfying and frustrating or can appear to be loving and hating is crucial. Another way of saying the same thing is that the earliest form of depression is the feeling which emerges, first, out of the realization that it is the same self that can both love and hate; secondly, out of the realization that the ego can hate and love the same object; and, thirdly, out of the realization that the same object or person can be gratifying or frustrating or can appear to be loving or hating. Whether or not this new feeling is tolerated—whether or not it is accepted as a fact of developing human experience—is certainly important. Tolerance is related at least to whether love is believed to be greater than hate or hate is believed to be greater than love. When the store of love is greater than hate love can be used quickly to overcome, to annul, to repair the effects of hate. Love can be used following separation from or death of a loved person to keep the memory alive and to keep alive the belief in a capacity to love and be loved, and consequently to believe that people worth loving and people who may love one still exist in the outer world. The more normal methods of dealing with depression thus arise.

The Genesis of Depression

There are many ways in which a partial and incomplete tolerance of a depressive situation may arise, and these lead to the many forms and symptoms of the abnormal depressive states of all degrees of severity. The many ways in which the intolerance of the depressive situation is shown are at least related to whether the angry impulses, acts, and imaginations are greater than the loving ones. If the anger is greater than the love—if the memories (or their symbolic substitutes) of the many aggressive acts, impulses, and imaginations are greater in strength than the memories of love—then arise hopelessness and depressive anxieties connected with the belief that one can do only bad things and that only bad can be expected of one. This may lead to a situation in which the self has to be destroyed to protect from one's badness the people and objects which go to make up one's inner and outer worlds. The self will be destroyed actually in suicide, or symbolically in a temper tantrum or a fit.

The situation I have tried to describe is the earliest example of one which will be repeated over and over again during later life. The changing ways the repetitions are

dealt with have much to do with personality development and character, but an essential relationship to the realization that the person can both hate and love, and that the same objects can be both loved and hated and believed to be lovable and hateable, remains and is crucial. Subsequent developments concerning the realization of one's self as a "whole person" and of other people as "whole people, and of one's self as of a certain sex and of other people each belonging to a certain sex, bring in many complexities, but the importance of the original situation remains. From the onset much—in fact most—of the developments mentioned have occurred unconsciously. Most of the normal ways of dealing with depression have developed unconsciously, as also have the various defences against depression.

The beginnings of depressive feelings related to the integrations already mentioned are concerned with the concepts of a continuing self and of other continuing persons. These beginnings are more in relation to what we would call in adulthood parts of a self or parts of another person. Nevertheless, soon the emphasis shifts as further development occurs to the conception of whole people—to the whole self and the whole people in the environment. Throughout life the conception of what a whole person is, the conception of what a human individual is or is worth, what a lifetime is or is worth, is continually changing and developing, and it is difficult to say what is the best or most useful formulation of a "whole person." At the present stage of human evolution, and being a part of our complicated discontented civilization, one would hesitate to generalize concerning "wholeness," but at least one can be tolerably sure that the study of what a "good whole person" is is intimately connected with the study of healthy and unhealthy ways of dealing with the depressive situation.

Connected with the integration which results in the belief in a whole self and in whole people (which often lasts more or less a lifetime with relatively little alteration) the conscience begins to develop in an elaborate form. One might have thought that the complicated nature of the good and bad conscience in depressive states would have forced psychiatrists long ago to realize the need for using methods of investigation which would bring to consciousness further details regarding their development. Analytic methods bring to consciousness details of what has come to be called the super-ego. The super-ego is both a great hindrance and a great help. Gradually more concerning its development has been elucidated. The super-ego is a much more elaborate, inhibiting, and stimulating unconscious construct than all that is connoted by a good and bad conscience. With adults, of course, the manifold implications of conscience and the super-ego have their importance in the symptomatology of depressive states. Nevertheless, depressive states and depressive anxieties (guilt, remorse, regret, etc.) can arise in connexion with simultaneous love and hate of part objects which are realized to have a continuing existence. In the analysis of depressed children and manic-depressive adults the content of analysis may deal mostly with memories (or their symbolic substitutes) of repetitions of coincident love and hate of part objects, but part objects which are realized to have a continuing existence. It is this situation which appears to contain the most significant ego and object relationship for the understanding of the genesis of depression.

The content of behaviour and speech of the depressed person deals with his attempt to discover a satisfactory way of dealing with the realization that his hate for some person is greater than his simultaneous love for the same person, without at the same time denying that it is he who feels both love and hate and without denying that it is to the same person that he feels both love and hate. The manifold

symptom-picture has to take account of the nature of the loving and hating impulses, acts, and imaginations at the early stage of development, when the integration already mentioned began. At this period the impulses, acts, and imaginations are predominantly oral. Nevertheless all organ activities which can reach consciousness may play some minor part at this time. Indeed, I think it is difficult to substantiate the view that there is an early period when some organs—for instance, the genital—play no part whatever.

Age of Onset

There is disagreement about the age at which depression can first occur, but I believe there is much evidence that it often occurs early in the first six months of life. It must also be remembered that the tests of reality which can be made at such a period are of an infantile type. The intensity and explosiveness of the infantile satisfactions and rages interfere with perception of reality, both inner and outer. The way each satisfaction and each rage is shown colours the outer world and the inner world by rapidly acting and by complicated types of introjection and projection. The effects of these mechanisms lead to many of the later complexities of depressive states. Regardless of how old the person is, if he has not dealt successfully with the infantile depressive situation he will be left throughout life with an infantile attitude to the dangers of realizing that he is a being who can both love and hate simultaneously and can feel both feelings simultaneously for the same person. If treated he may be brought face to face with the intensity of the complicated feelings appropriate to his present-day situation and may for a time suffer more severely while he is learning to deal healthily for the first time with depression.

In such a brief presentation little other than conclusions can be put forward and nothing can be said about the earlier analytic views. The conclusions I have mentioned do not contradict these earlier views. They do little else than elaborate earlier views in the developmental sense. Nevertheless a few brief sketches of the sort of patient whose study has led to these conclusions can be given.

Illustrative Cases

Case 1.—A boy aged 2 years and 1 month became severely disinterested in everything and everybody, following a seemingly successful weaning at 9 months. He became constipated. He was slow and quiet, and showed no interest in learning to speak. During seven months' treatment he became able to deal more normally with the depressive anxieties and situation already described. The subsequent mood-changes were such that in retrospect it was easy to recognize his earlier state as a severe anergic depression. In analysis he showed by play florid content of depressive type. He did not speak a word during analysis, but began to learn to speak at home. By play he could show much more complicated content than he could expect to speak of for years. He did nevertheless make tests of oral projective activity by yelling in rage once and by making a few sounds easily recognizable as signs of considerable pleasure.

Case 2.—A woman of 20, who had for at least 10 years gradually become more disinterested and depressed and later suicidal, showed during more than four years' treatment how homosexuality and severe masochistic and sadistic imaginations were the unhealthy attempts to cope with her forgotten wish to deal with the effects she believed her early aggression has had on her mother. Following much noisy dissatisfaction during the first month of her life, during which she had been breast-fed, she was seemingly satisfactorily weaned. She showed no open oral aggression from the first month of life till many months after the beginning of her treatment. Only after learning to deal with almost simultaneous or at least very rapidly alternating hateful and loving impulses and acts of extreme intensity during treatment, which occurred in a hospital environment, was she able to begin to use her adult capacities to deal

with the implications of her previously persistent infantile depression. During the crucial stages of her treatment her emotions were nearly, if not indeed quite, epileptic in intensity. During treatment stuporous states were interrupted by attacks of rage which, I think, were related to epileptic furor. Such rages were followed by disturbances of consciousness. Later intensely energetic loving outbursts occurred. These gradually lessened. The alternating love and hate gradually lessened in intensity as the depression connected with the realization that both were, had been, and would be felt towards the same people became more tolerable.

Case 3.—A man of 59 developed an agitated depression. During treatment he showed how a deep attachment to a grandfather in infancy might have led to the development of adult homosexuality had the grandfather not died at 60, when the patient was 4. The patient did not grieve openly then, but his super-ego became to a large extent modelled on this grandfather. During treatment, when he realized the degree of his identification with his grandfather and when he realized that he had unconsciously feared his own death at 60, he began to be able after the lapse of 55 years to mourn the death of his grandfather openly. He then became able to plan a life modelled on a scheme based more on the memory of the ambivalent love and hate for his own mother, whom he had ceased to feel for in his infancy when he gave his love to his grandfather. Had he coped more healthily with depression in infancy he might not have become so pathologically attached to his grandfather. Thus he might have avoided a severe depression at 59, when his age was nearing that at which his grandfather died. Such a history demonstrates how difficult it would have been to predict, for instance, when he was 40, that he was seriously predisposed to an illness at 59.

One could also sketch many failures, but unfortunately the chief point with regard to the psychopathology of psychoanalytic failures is that the data on which one might base inferences to explain why they were failures cease to be collected. Here I would make a plea to those who have under observation depressed patients who have had analytic treatment and are still unable to deal healthily with depression to report the later developments. I am confident that the patients' previous analysts would co-operate.

Conclusion

I do not think I can do better than suggest that the implications of the simple formula already outlined regarding the onset of depressed states be investigated fully. I restate the formula: out of the realization that at one and the same time it is possible for a person to love and hate, and out of the realization that such love and hate can be felt for one person, emerges the human capacity for depression, both normal and abnormal. The vicissitudes of the imbalance between the loving and hating impulses determine the normal or abnormal subsequent development with regard to the capacity to deal healthily with depression.

Many students find *Essentials for Final Examinations in Medicine*, by John de Swiet (J. and A. Churchill, 9s.), of value during the harassing weeks before their final examinations, and it has now reached a third edition. No great changes have been made, but the author has brought it up to date by including new sections on penicillin, pellagra, and other changing aspects of medicine, and has added an index. It is no light undertaking to attempt to compress even the salient features of general medicine into so small a compass, but the author has succeeded reasonably well. A few minor inaccuracies are present, but for the most part the information is sound and clearly presented.

**LUTON CHILDREN'S HOSPITAL,
HOUSE SURGEON (B2)**

Applications are invited from registered medical practitioners, male and female, for the appointment of House Surgeon (B2), vacant mid-April, 1948. Salary at the rate of £200 per annum, with full residential emoluments. Ear, Nose and Throat Department
Applications are invited from registered medical practitioners (male and female) for the appointment of House Surgeon (A) Ear, Nose and Throat Department, and to act as Casualty Officer during mornings, non-resident, vacant now, including practitioners within three months of qualification who are liable to service under the National Service Acts. If held by a practitioner who is liable under these Acts, the appointment will be for a period of six months. Salary is at the rate of £300 per annum. Applications, with copies of two recent testimonials, should reach the undersigned immediately.—L. Palkhouse, Secretary and Manager.

RUNWELL HOSPITAL, near Wileford, Essex (East Ham and Southend-on-Sea Joint Mental Hospital) (1,032 beds)

SENIOR RESIDENT PHYSICIAN

Applications are invited for the post of Senior Resident Physician at the above-named hospital. Salary £750 per annum, rising by £25 to £850 p.a. cost-of-living bonus at present £49 16s. 8d. with emoluments consisting of house, light, fuel and garden produce valued at £159 19s. 4d. per annum. The appointment is subject to the provisions of the Asylums Officers' Superannuation Act, 1904. Application forms, together with further particulars, obtainable from the Physician Superintendent.

ROYAL ALBERT EDWARD INFIRMARY AND DISPENSARY, Wigan

HOUSE SURGEON (A)

Applications are invited from registered medical practitioners for the appointment of a House Surgeon (A), now vacant. Salary £150 per annum, with full residential emoluments. Practitioners within three months of qualification and liable under the National Service Acts may apply, when appointment will be for a period of six months; otherwise it may be extended for a further period. Applications should be sent to the undersigned as soon as possible.—A. Stanley Brunt, General Superintendent and Secretary.

ROYAL SUSSEX COUNTY HOSPITAL Brighton

HONORARY MEDICAL REGISTRAR

Applications are invited for the appointment of Honorary Medical Registrar from candidates who possess the necessary medical qualification. Under the hospital's present rule, the successful candidate may be appointed for a term of three years. Applications must reach the Secretary-Superintendent by April 5, 1948.

ease and the writing of 82 letters to consultants and hospitals concerning patients.

In all 70 patients were referred for a second opinion and 13 sent hospital direct, as immediate emergencies. Of the visits, 16 were ght-calls between 10 p.m. and 8 a.m.

An attempt has been made to classify the types of illness on which the patients were suffering, though it speedily became obvious that such a classification could, at best, be only a very rough one and that while certain categories could be clearly defined others tended to overlap considerably. A classification of systems of the body was also undertaken. The results are given in tabular form below, excluding all midwifery.

Illnesses		Systems of the Body	
acute general infections ..	25.8%	Cardiovascular system ..	9%
acute local infections ..	12.7%	Respiratory tract ..	23.5%
chronic infections ..	3.1%	Digestive tract ..	14.8%
neurotic conditions ..	7.7%	Skin ..	10.5%
neurotic conditions ..	13.9%	Bones and joints ..	7%
neurotic conditions ..	23.2%	Muscles ..	4.1%
neurotic conditions ..	2%	Central nervous system (including functional nervous disorders) ..	9.4%
neurotic conditions ..	6.3%	Genito-urinary system ..	5.3%
oplasms ..	1%	Glands of internal secretion ..	1.5%
ergic conditions ..	1.6%	Connective tissues ..	3%
prostitis and allied states ..	2.7%	Eyes ..	1.9%
		Ears ..	2.5%
		Throat ..	6.7%
		Haemopoietic system ..	0.5%

In respect of the original object of the survey—the estimation of the amount of neurotic illness—it rapidly became clear that quite apart from the clear-cut cases of almost pure neurosis a very large number of the patients suffering from a definite organic complaint were also affected by a strong subjective element, due to their anxiety about their health or anxiety about the effect of their illness on their economic conditions. In the table above the figure given for functional nervous disease of 1% tells only a part of the tale, as no patients with any demonstrable organic condition were included.

It seems obvious that the amount of neurotic illness seen by a general practitioner is very considerable, but that no reliable estimate can be given inasmuch as standards of classification are most impossible to set up, and the recognition of neurosis will itself tend to vary with the outlook and temperament of the doctor himself.—I am, etc.,

Aldershot.

H. BOLTON TIPLER.

True Hermaphroditism

SIR.—Dr. A. P. Cawadiaz (Jan. 31, p. 229) would appear to be under some misunderstanding concerning the nature of hermaphroditism in the animal kingdom. Even the humble hermaphrodite worm might turn at being described as a "double animal." In reply to Dr. J. R. Edisbury (Dec. 27, 1947, p. 1056) must be said that the whole subject is a very large one and it cannot be dismissed in a few lines.

As is well known, the sex of an animal depends primarily on its genetic constitution—i.e., the sex-chromosomes when these are known to exist. But for the full development of a functioning sexual animal the whole hormonal apparatus is essential. Hormones and other conditions, however, can override the original sex chromosomes and cause a sex-reversal.

A definition of terms might not be out of place here. There are three groups:

1. True permanent *hermaphrodites*, in which ovary and testis remain together and function throughout life—e.g., earthworm;
2. *Sex reversals* in which the animal starts as one sex and passes through a hermaphrodite stage to the other sex—e.g., the Buff Orpington hen (see below);
3. Those individuals with the gonads and sexual apparatus of one sex and some or all of the accessory organs and hence characters of the other sex—e.g., the mammalian *intersexes*.

Unisexuality is the primitive condition, and not hermaphroditism. Dr. Cawadiaz suggests. For example, in the invertebrates it is more specialized forms in any groups which exhibit this phenomenon, or where it occurs in a whole group this is entirely specialized. In the *Crustacea* the sessile barnacles are hermaphrodites and also many parasites. In general the phenomenon has evolved under conditions where fertilization would be difficult if unisexuality prevailed. It is not confined to such types, as is shown by the few vertebrate hermaphrodites such as the bony fish

Serranus, where a testis is present in the wall of the ovary and self-fertilization takes place. These are all examples of Group 1 above.

Group 2 is illustrated by the now famous Buff Orpington hen which, after a blameless life of egg-laying and chick-rearing, at the age of 3½ years stopped laying, grew cock feathers, started crowing, and was successfully mated with a previously infertile Buff Orpington hen. At necropsy the ovary was found to be replaced by tumour tissue and a small amount of testicular tissue was present in the ovary. This tissue had produced the viable sperm and incidentally the secondary sexual characters. This same effect may be produced by outside agents. The crustacean parasite *Sacculina* is able to convert a male crab into one with female characters. It has been shown that in doing so it is able to use the products of the "female" crab's metabolism for its own ends.

In the case of the worm *Bonnelia*, Baltzer (1925) has shown that sex is determined by pure accident of situation. The larva at a certain stage sinks from the surface. If it falls near the proboscis of a female *Bonnelia* it becomes a male. If however it falls anywhere away from this influence it becomes a female. It has been shown that the female proboscis possesses a chemical substance which dominates the sexual character of the form which comes into contact with it.

Under Group 3 come all those cases in mammals, including man, which although predominantly of one sex do nevertheless exhibit certain characters of the other sex. In the case of cattle a co-twin to a male becomes a freemartin—i.e., a female which never becomes a functional one. This has been shown to be due to the earlier elaboration of the male sex hormones by the male twin in utero (Lillie, 1917).

In all higher vertebrates both male and female ducts are present during development. In most cases one develops more rapidly than the other and only vestiges of the opposite sex are left. This is not, however, always so, and in some cases, in which one may postulate a time factor, much more of the organs of the other sex develops, and even the gonad may do so. Hence the possibility of intersexes. These commonly occur in goats and pigs. In mice they are less common, and it may be suggested that here the sex-determining mechanism is more stable.

Goldschmidt (1931) in his work on moths has obtained evidence for the existence of "strong" and "weak" male and female genes. In his elaborate experiments he was able to breed types with varying grades of "maleness" and "femaleness." His theory suggests that sex and intersexuality are largely determined by a balance or lack of balance in the strength of these male and female genes. Whether this is applicable to vertebrates we do not know, but it may well be so.

Dr. Edisbury and others interested might consult any of the following books for a full account of this very large subject: Goldschmidt, R., *The Mechanism and Physiology of Sex Determination* (Methuen, 1923); Darlington, C. D., *Recent Advances in Cyrology* (Churchill, 1937); Crew, F. A. E., *Sex Determination* (Methuen, 1933); Baker, J. R., *Sex in Man and in Animals* (Methuen, 1926).—I am, etc.,

King's College,
Newcastle-upon-Tyne.

SIR.—I am indebted to Dr. A. P. Cawadiaz (Jan. 31, p. 229) for his informative iconoclasm and also for directing my attention to his *Hermaphroditism*, which I regret to say I have not yet read. In extenuation, your annotator (Nov. 22, 1947, p. 828) seems to have been in the same lamentable position.

There does not seem any immediate prospect of a convenient qualitative test for human y chromosomes, or a roughly quantitative test for x, either of which would reveal the true or genetic sex. Perhaps someone who knows just what possibilities exist, if any, will write an article on the subject, not forgetting the forensic aspects—e.g., male heirs, etc.—I am, etc.,

Horton, Cheshire.

J. R. EDISBURY.

Homoeopathy

SIR.—My attention has just been drawn to Dr. D. W. Winnicott's letter (Feb. 14, p. 313) in which he states among other things that "homoeopathy has not been accepted by the profession on scientific grounds."

As a member of the profession who practises homoeopathy, may I point out to Dr. Winnicott that homoeopathy has never

been tested scientifically by "the profession," but has been rejected by it simply through prejudice without any proper trial. We homoeopathic physicians have repeatedly asked "the profession" to put the method to the test, and they have always refused.

We therefore welcome the opportunity which seems to be presenting itself in the near future of getting our method of therapeutics put to the test, which we have no doubt it will pass; and so the "over a million people" in this country who prefer homoeopathic treatment will be able to obtain it under the National Health Service Act.—I am, etc.,

London, W.1.

ALVA BENJAMIN.

Juvenile Delinquency

SIR,—Dr. Eustace Chesser (March 6, p. 475) makes the statement that "virtually all juvenile delinquents are made, not born," and prescribes the omnibus remedy of "short and severe punishments, followed by psychological treatment," as an alternative to "three years of comparatively negative confinement in an approved school."

Such a view ignores increasing knowledge of genetics and of the hereditary factor in disorders of conduct. It also overlooks the active contribution that the approved schools are making to the study and understanding of the factors which lead to juvenile delinquency, quite apart from their role in re-establishing as normal members of the community a high proportion of the young people whose training and re-education they undertake.

The urgent necessity advocated by your leading article (Jan. 31, p. 203) for further investigation into the efficacy of different methods of treatment as judged by the after-histories of cases of different types should receive the full support of all scientific workers in the field as being a direct means of determining the underlying causes and hence contributing to the prevention of juvenile delinquency.—I am, etc.,

Liverpool.

MURIEL BARTON HALL.

Child Guidance and Youth Organizations

SIR,—I have read with interest the letter of Dr. D. T. Maclay (Feb. 21, p. 368) on the need for liaison between psychiatric workers on the one hand and youth movements on the other. The London Union of Mixed Clubs and Girls' Clubs has now had for about three years the services of an honorary consultant psychiatrist and has found them of very great value. Our consultant visited clubs of different kinds and spent some time familiarizing herself with one in particular before undertaking to advise our leaders.

This organization has 22,000 boys and girls in its clubs in Greater London. Among them are naturally some "difficult" adolescents, but I would emphasize that it is not only the exceptional case that can benefit from psychiatric advice. We are still constantly learning how to make the wisest provision for normal young people growing up in our society.

All our students in training for leadership have had the advantage of lectures and tutorials from our consultant; and some of our best and most experienced leaders, too, have told me that it is a refreshment of spirit and an illumination of the mind to talk to our psychiatrist. Many people find club leadership as exhausting as it is rewarding, and the services of a psychiatric worker may be directly helpful to the leader as a person as well as in his or her professional capacity.—I am, etc.,

MARJORIE TAIT,
Organizing Secretary,
London Union of Mixed Clubs
and Girls' Clubs.

London, S.W.4.

SIR,—I would like to protest against the suggestion implicit in Dr. D. T. Maclay's letter (Feb. 21, p. 368) in which he couples the increase in juvenile delinquency with the spread of child-guidance clinics, and accuses child-guidance clinics of ignoring youth organizations such as Boy Scouts, Church Lads, etc. He does not mention the war, but this has been and will be for many years the chief cause of the rise in delinquency. Broken homes, marital discord, and prolonged separation from parents, especially in the first six years of life, play a large part in inducing the delinquent frame of mind. In these circumstances the normal love relationship between child and parents is disturbed, so that the child lacks the incentive to

model himself on his parents and accept his parents' standards. Less frequently the parental standards are themselves low so that the delinquent child is merely imitating his parents. The increased marital infidelity and divorce which occurs in war-time, and the separation necessitated by evacuation, is one of the commonest causes of delinquency now, and often the delinquency dates from evacuation or the return from it, a most difficult period for a child.

One of the functions of a child-guidance clinic is to re-establish a normal love relationship between the child and parents, so that the child can again derive pleasure from pleasing them. This is done by work with the parents, play therapy with the child to get rid of the child's resentful attitude, and of course by helping the child to find socially acceptable outlets for his energy, such as the clubs Dr. Maclay mentions. It is no use preaching to delinquents. They simply take no notice, like a girl of eleven I have recently seen, who regularly attends Sunday school and has made a practice of stealing money from the Sunday-school teacher's handbag after the service.

Unfortunately child-guidance clinics are far too few to cope adequately with this difficult problem, and I agree with Dr. Maclay that all encouragement should be given to youth clubs. It is however an odd point, as Healy and Bronner have shown, that delinquents are more often regular club members than their non-delinquent siblings. But I can assure Dr. Maclay that all good child-guidance clinics do co-operate with social clubs and youth organizations, and every encouragement is given to the children to join them.—I am, etc.,

London, W.11.

FELIX W. BROWN.

School Ophthalmic Service

SIR,—I think from Mr. S. Black's reply (Feb. 21, p. 368) that he must have read my letter in somewhat of a hurry. I emphasized that every Devon County Council school child had a visual acuity test every year, the most important group being that of the school entrants. I am quite sure that Mr. Black would find that children of 4 to 5 years of age, when tested by reliable and scientific methods, are quite unable to attain the 6/6 standard when there is even a low error of refraction and definitely not when there is a "fairly high error."

It is for this very reason that this group is considered so important, before gradually increasing close work has produced ciliary over-action in cases of hypermetropia, which cannot be spotted by visual acuity tests when the children reach 7 or more years. Youngsters who are too shy, dull, uncooperative, or unable to carry out the test are referred, with all those failing to attain the required standard, for full ophthalmic examination, of which the actual refraction is not the most important part.

My so-called defence of Devon County Council arises from the fact that the ophthalmic scheme in operation there is the one of which I have complete and intimate knowledge, and I am therefore in a position to refute Mr. Black's allegation at any rate as far as this area is concerned.—I am, etc.,

Exeter, Devon.

MARGARET L. FOXWELL.

An Arab Custom

SIR,—We believe the following may be of interest to your readers. While visiting the newly built American Mission Hospital in Doha, capital city of the Qatar Peninsula, Arabia, we were informed of the following practice employed by the Arab women after parturition.

When the placenta has been expelled the vagina is packed with common salt for two to three days in an endeavour to produce contraction of the vagina to the nulliparous state. This is usually followed by fibrosis of the vaginal canal and often atresia of the vestibule. As a result subsequent labours prove difficult, usually necessitating episiotomy, which formerly the Arabs practised among themselves.

As the Arab is polygamous by nature, this practice is an attempt by the wife to retain her former position in the eyes of her husband.—We are, etc.,

H.M.S. "Challenger,"
Persian Gulf.

P. I. RUTHERFORD,
Surge. Lieut., R.N.V.R.

POINTS FROM LETTERS

Stand Firm

Dr. J. R. SALMOND (Burton-on-Trent) writes: The profession has spoken in no uncertain voice. Now, B.M.A., stand firm! We are all behind you and expect a lead. Don't give way or compromise—it is too dangerous. Local study circles must be fully organized and must have a definite policy. Our patients look to us to refuse service under the Act as it stands and to maintain our professional freedom. Think of what public apathy cost Germany in the '30s. We must cling to our liberty. . . . One thing now is certain. Since we have shown very clearly that the whole of the profession is opposed to the Act as it now stands in this country, the B.M.A. must have ready some concrete proposals for a more reasonable health scheme which can be put forward to Mr. Bevan as an alternative in the knowledge that the doctors would willingly join together in working it to the common good of all.

Compensation after July 5

Dr. PETER E. MORRIS (Hayle, Cornwall) writes: Apart from the principles involved the financial worry of most of us is the fact that at present we must enter the scheme on or before July 5 or go without compensation even if we join in later on. If the Minister were prepared to buy our practices, or in other words if spot cash were offered for goodwill, whenever a practice was incorporated in the N.H.S., there would be nothing for us to worry about on this score. One sees of course that this would destroy what the Minister hopes is a trump card, but his refusal to agree so it would be absolutely indefensible. . . .

Accepts Service

Dr. S. GILFORD (Reading) writes: I should like to apologize to Dr. R. H. SCOTT (Feb. 21, p. 360) for one mistake in my letter. In my *Medical Directory* for 1944 I found that a Dr. Ronald Hadley Scott, living in Hook, Basingstoke, was in the partnership of Cox, Scott, and Sharkey, of Basingstoke. Dr. J. A. Sharkey signed the letter, but I found that there was another Dr. R. H. Scott (Ronald Gifford), of Newcastle-upon-Tyne, who has apparently settled in the district. . . . I should like to add a few words about the plebiscite. I did not answer A—"I approve of the National Health Service Act in its present form"—because it is evident that no one can approve of it without amendments in the future. I believe that a salaried service is the only form which will provide a satisfactory service when the health centres are established. Financial competition will make full co-operation impossible. I am willing to accept service under the Act in its present form and to hope for improvement in the future. I may add that any amendment of the Act now would invalidate the plebiscite and leave anyone who signed that plebiscite free to alter his mind before July 5.

Plebiscite Warning

Dr. T. J. CROFT (Birmingham) writes: Services, permanent commissions, 16-1 against. This result, plus the figures for all salaried groups, must have surprised more G.P.s than myself. It surely is a grave warning against that type of service and should make even those who voted in favour think again. In the past temporary serving officers expressed their opinions on many subjects under a *nom de plume*. Some of their more experienced colleagues could do the profession a great service and stiffen our morale by giving us some of the "facts of life" in a State service just now. In the meantime I personally await with confidence further guidance from our Representative and Negotiating bodies. We have more to fear than loss of compensation—think of all the regulations yet to be inflicted on us. Dr. Thomas J. Agius (Feb. 21, p. 362) quotes from a sample.

Doctors' Wives

Mrs. D. FRASER (Dioxford, Hants) writes: As soon as the goodwill of my husband's practice passes to the State (with or without compensation) I intend to discontinue my almost full-time unpaid job of administrative assistant to him. A railway engine-driver's wife takes no part in administering the railways any more than a Coal Board official's wife does in running the mines, and I feel that under the new dispensation I ought to be equally absolved from having to help in making Mr. Bevan's scheme a success. . . . I suggest therefore that this matter should be strongly represented to the Minister, whether or not further negotiations take place, and also that the delegates at the meeting of the Representative Body on March 17 should give some thought to it in deciding the future action of the Association.

Prickly Heat: A Simple Remedy

Dr. H. J. KINGSTORY (Bulawayo, Southern Rhodesia) writes: If Dr. C. J. Wilson (Jan. 10, p. 76) will refer to Martindale's *Extra Pharmacopoeia* (22nd edition, vol. I, p. 599) he will find that lotio

hydrargyri perchlor., 1 in 1,000 solution with 2 in 1,000 hydrochloric acid, is recommended for prickly heat. I also have used this simple remedy with success, but can any reader tell me what is the effect of adding hydrochloric acid to the perchloride solution?

Relief of Nervous Tension

Dr. C. HORWITZ (London, N.1) writes: As an aftermath of the war there remains a great amount of residual nervous suffering among the population. That this is so is demonstrated by the frequent announcements over the wireless of the loss of dangerous drugs, mostly phenobarbitone, which are so largely prescribed as sedatives. I would like to draw attention to a method of relieving nervous strain and tension from which I myself and many of my patients have greatly benefited. It is by means of the method of progressive muscular relaxation as advocated by Dr. Edmund Jacobson, of Chicago, in his book on the subject published in 1929. Indeed, adequate training in muscular relaxation may be regarded as a prophylactic against the onset of a nervous breakdown for which rest is so often prescribed. But the patient must be taught how to rest and how to release the nervous tensions in various parts of his body. The method needs to be practised to become perfected, as one practises the piano or playing golf. To quote from an article from one of our leading psychologists and a great exponent of the method, Dr. William Brown: "The recuperating effects of rest and progressive muscular relaxation not only in mental and nervous disorders and diseases but also in physical illness, and in the normal stress and strain of life, have been admitted, indeed emphatically asserted, by medical practitioners throughout the ages."

The Blood Picture in Chicken-pox

Dr. H. ANGELL LANE (California, U.S.A.) writes: Dr. Thomas Parkinson's very interesting paper (Jan. 3, p. 8) prompts me to draw attention to an easily ascertainable fact, mention of which, however, I have not seen in the ordinary textbooks.

In the great majority of cases of chicken-pox will be found from the second to the seventh day of the rash only, (1) a "drift to the left" out of all proportion to the severity of the case, and (2) 2% to 7% Türk cells. These cells are generally smaller than those seen in cases of German measles and disappear from the picture after the seventh day, with the peak on the fifth (I have seen 12% then). I have found them rarely in cases of herpes zoster; in only one case, however, was this followed by chicken-pox in another member of the family.

Asthma and the Inhaler

Dr. A. W. PATERSON (Ipswich) writes: I have just seen with pleasure the letter by Dr. Paul Wingate (Jan. 31, p. 226) giving expression of his high appreciation of inhalations (for spasmodic bronchial asthma) of the bronchovodyrin type. His letter represents almost exactly my own opinion regarding such of these preparations as I have used now for almost eleven years. Having read recently, and a few months ago, adverse opinions of such preparations on account of their effect on the bronchial mucosa and its cilia, I should like to support Dr. Wingate by stating the great benefit I have received during these eleven years without having observed any harmful effects whatever. Like Dr. Wingate, I feel the inhalations can to a great extent replace hypodermic injections, their effect being manifest in relieving an attack and in most cases aborting it in a few minutes. Prior to their use I had to rely on adrenaline injections, sometimes several times a day, and of course was thankful enough for them.

You may remember that I wrote to the *British Medical Journal* regarding the very great benefit I had received from these inhalations as I was anxious to share my means of relief with the many who suffer the extreme discomfort of severe asthmatic attacks. I felt that these bronchovodyrin type inhalations, proprietary or not, should be more widely used and known.

Ovarian Cyst in an Infant

Dr. T. J. M. GARRO (Newbridge, Meath) writes: When conducting a post-mortem examination recently on a five-month-old baby, which proved to have died as a result of inhaling its own vomit, I discovered a very large thymus gland which completely covered the whole of the heart and was almost as large as one of the lungs.

I also discovered a pelvic cystic swelling which I thought might be of interest. This was a freely movable yellowish cyst about the size of a small hazel nut, situated near the end of the left Fallopian tube. The right tube was quite normal. I took the swelling to be an ovarian cyst. I have no access to advanced gynaecological literature and am unable to look up any references to previous similar findings, but I thought it worth my while to report my findings to you in case they may be of interest to other members of our profession.

The only other abnormality I detected was some enlargement of the blood vessels between the stomach and the transverse colon causing slight adhesion between these two organs.

Obituary

R. D. BEATSON HIRD, M.D., F.R.C.S.Ed.

When Robert Dennis Beatson Hird died on March 2 at the age of 67 the Midlands lost an outstanding figure in ophthalmology, a loss which will be felt keenly by colleagues, friends, and patients alike.

Beatson Hird received his medical education at the University of Birmingham. He and Sir Leonard Parsons were students together, and he graduated M.B., Ch.B. in 1905, proceeding M.D. a year later, and taking the F.R.C.S.Ed. in 1909. He was a native of Birmingham, and practically the whole of his professional life was spent in that city. He gave much of his time to public work, and among the many appointments that he held were those of honorary ophthalmic surgeon to the General Hospital and later to the Birmingham United Hospital; honorary surgeon to the Birmingham and Midland Eye Hospital; and ophthalmologist to the Birmingham Education Authority. He was also lecturer in ophthalmology to the University of Birmingham until 1945. During the war he served as Midland regional adviser in ophthalmology to the Ministry of Health.

A man of abounding energy and enthusiasm, he gave of his best at all times, both in his public appointments as well as in his private practice. From time to time he contributed articles to the medical journals, but it was in the clinical side of his work that his main interest lay. To this he brought keen observation and a meticulous attention to detail—a combination which rendered his work of the highest order and which was an example to those who worked under him. Nor was his view of ophthalmology a narrow one. He regarded it as only a part of the wider field of medicine, and in the sphere of medical ophthalmology his knowledge was unsurpassed. His opinion and advice were frequently sought by colleagues engaged in general medicine and surgery, and often his report gave the clue to diagnosis in difficult cases. He was a successful teacher, with a facility for imparting to his students a clear picture of the essentials of his subject. Many men now engaged in ophthalmic practice, not only in this country but in the Colonies, were once his house-surgeons and owe much to him for his advice and instruction at the outset of their careers.

His great enthusiasm for his work remained unimpaired throughout the years. In the early days of the war he suffered from a severe heart attack, but his enthusiasm and his strong sense of duty compelled him to return to full work after a few months. Nor did he then spare himself, and it would be difficult to overestimate his services to members of the Forces and to civilians who sustained eye injuries. Outside his profession he was a keen golfer until illness precluded active exercise, and among other hobbies was an interest in astronomy and a fondness for literature. There is no doubt, however, that his family life and his work were the main interests in his busy life. Beatson Hird will long be remembered both for his professional skill and for his sterling personal qualities.—C. R.

CHARLES H. RIVERS, M.D., M.R.C.P.

The march of events makes it improbable that provincial medicine will see again a man of the type or stature of Charles Rivers, who died on Feb. 28 at the age of 76.

Educated at King's College School and St. John's College, Cambridge, Rivers took the B.Sc. in 1894 and a second class in the natural science tripos in 1895. In the course of a distinguished undergraduate career in the medical school of Middlesex Hospital he held university and Broderip scholarships. He obtained the conjoint qualification in 1898 and was subsequently house-physician to Sir Richard Douglas Powell and Sir J. Kingston Fowler, and later demonstrator of pathology at the medical school. With a colleague he was co-founder of the *Middlesex Hospital Journal*. He took the M.R.C.P. in 1901, proceeded M.D. in the following year, and was later awarded the honorary degree of M.D. by Adelaide University.

After experience as a surgeon in the Boer War, Rivers worked in Australia from 1903-14 as honorary physician at the

Adelaide Hospital and the Kalyra Sanatorium, and later as tutor in medicine, and examiner in forensic medicine at Adelaide University. During this period he made a close study of pulmonary tuberculosis, being among the pioneers of artificial pneumothorax therapy, and of haematology, and published some thirty papers on clinical and pathological subjects. It is of interest to note that he was treating myeloid leukaemia with x rays in 1905. In 1914, despite an assured career in Australia, Rivers decided to return to England. After three years as tuberculosis officer to the Kent County Council he settled in general practice in Redruth in 1917, joined the staff of Redruth Hospital, and became part-time medical officer of health for the district.

He brought to general practice a rare and varied experience and a determination to apply it. He founded his own clinical laboratory and maintained its work for thirty years. He built up adequate physiotherapeutic and diagnostic x-ray equipment and he started the diagnostic and therapeutic x-ray work at Redruth Hospital. An acknowledged authority on the silicoes of metal-miners, he combined in his person the offices of consultant and practitioner, physician, pathologist, radiologist, and hygienist, and filled them all with real competence. A life-long student, it is typical that in his seventh decade he studied, and became proficient in, electrocardiography. Rivers possessed the gifts of orderly method and a capacity for sustained effort. He made decisions carefully, and did not alter them lightly. An individualist, he was fervent, even choleric, in controversy but ever courteous and jealous for the dignity of his vocation.

Outside his work he was a man of wide culture and a good classical scholar. An accomplished musician, the founder of the Cornwall Symphony Orchestra, which he directed and conducted personally, was an achievement he held dear. His fortitude in his final infirmity was as impressive as was his passion to work in spite of it. His colleagues will long respect the memory of one whose death marks an epoch and whose manifold attainments are unlikely again to come within the scope of one man. Their sympathy is extended to his widow and five sons, of whom one is a doctor.—L. W. H.

Dr. JOHN McEWEN DALZIEL, who died in London on Feb. 2 at the age of 75, was born in India and educated at Doherty Academy and Edinburgh University. He graduated M.B., Ch.B. in 1895, proceeded M.D. in 1903, and took a B.Sc. in Public Health in the following year and also the diploma in tropical medicine. Dr. Dalziel joined the West African Medical Service and became finally deputy director of sanitary services on the Gold Coast. He wrote several books on the plant life of West Africa and also *A Hausa Botanical Vocabulary*.

Dr. WILLIAM MINTY BADENOCH, of Leyton, London, E., died on Feb. 22 at the age of 64 after a short illness. He was born in Banffshire, Scotland, and educated at Aberdeen University where he graduated M.B., Ch.B. in 1908. After some experience of hospital work and of general practice he settled in Leyton in 1912. Two years later he joined the R.A.M.C. and saw service in France, Gallipoli, and Mesopotamia. He was mentioned in despatches on two occasions, was severely wounded, and left the Army with the rank of major. After the war he went back to Leyton and gradually built up a large practice. He was for many years the "J" Division police surgeon, and for six years he acted also as deputy coroner for the Metropolitan district of Essex. During the recent war he worked at a temporary surgery in part of the Leyton Vicarage. Dr. Badenoch was chairman of the South-west Essex Division of the British Medical Association in 1928-9. He was vice-chairman of the parochial church council for many years, and he acted as medical officer to the 35th City of London Battalion of the Home Guard. He is survived by a widow, a daughter, and a son, Dr. John Badenoch.

Dr. DOUGLAS ROBERTSON died at his home on March 6 at the age of 49, after a fall earlier in the day. He had been ill for about two years previously. Dr. Robertson graduated M.B., Ch.B. at Leeds in 1921, and was a son of the late Dr. H. M. Robertson, who was in practice in Roundhay, Leeds, for many years. For thirteen years after qualifying he practised in Longtown, Cumberland, where he was medical officer of health for the district. He had been in practice at Thorncliffe Dale since 1934. He was on the staff of the Malton Cottage Hospital, and was medical officer for the Allerston district.

Crookes Halibut Oil

in *new*, palatable, miscible
form for bottle-fed
infants

The richest sources of vitamins A and D — the livers of fish — have always had the disadvantages of strong taste and difficulty of mixing with milk. Crookes have now developed their new Halibut Oil *Emulsion* for Infants to overcome these difficulties.

This new Emulsion, which is basically the highly potent Crookes Halibut Oil, mixes immediately with milk and is agreeable to take. Three drops in the infant's feed, for only 4 of the daily feeds, provides 3000 I.U. of vitamin A and 800 I.U. of vitamin D.

CROOKES HALIBUT OIL EMULSION FOR INFANTS

Obtainable only from Chemists — 3/6d a bottle.

Literature available upon request.

THE CROOKES LABORATORIES LIMITED · PARK ROYAL · LONDON N.W.10

Soothing relief for HEAD COLDS and NASAL CATARRH

- 'ENDRINE' for head colds and catarrh.
- 'ENDRINE' Mild for children and chronic cases of long standing.

Is provided by 'Endrine' Nasal Compound. The application of four or five drops to each nostril shrinks inflamed tissue and promotes easy breathing.

'Endrine' Ordinary formula Ephedrine 0.75% w/w, Menthol 0.5%, Camphor 0.5%, Eucalyptol 0.5%, Oleum Ricini 0.35%, Light Liquid Paraffin ad. qs. 100%

'ENDRINE' Nasal Compound

Medico-Legal

LIBEL ACTION BY MR. MATTHIAS ALEXANDER

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

In the Rand Division of the Supreme Court of the Union of South Africa, on Feb. 16, Mr. Justice Clayden began the hearing of an action for libel brought by Mr. Frederick Matthias Alexander, of London, against three medical men: Dr. Ernst Jokl, Physical Education Research Officer to the Union Education Department, Dr. E. H. Cluver, Director of the South African Institute for Medical Research at Johannesburg, and Dr. B. Maule Clark, of Houghton, Johannesburg, as editors of *Manpower*, a biannual scientific journal published in Pretoria by the Government Printer and circulating throughout the Union.¹

Mr. Alexander alleges that the defendants published an editorial article and an introductory note, entitled "Facts and Phantasies," to a further article implying that he made false claims as to the scientific value of his technique, and that from the scientific point of view the technique was contemptible and nonsensical; that he was untruthful and dishonest, a charlatan and a quack; that he had given the public dangerous and criminally irresponsible advice; that for personal gain and to attract people he had held out false promises of the benefits to be derived from following his teachings; and that he was mentally deranged and unbalanced. He further alleges that he has for fifty years been carrying on for reward the profession of teaching and expounding his technique, and that from the offending publication he has suffered damages in the sum of £5,000. The defendants admit publication, deny defamation, and alternatively plead truth and fair comment in the public interest.

Mr. O. Pirow, K.C., appearing for the defendants, explained that the case for the defence was that the matter complained of represented an evaluation of Mr. Alexander's four books *Man's Supreme Inheritance*, *Constructive Conscious Control*, *Use of the Self*, and *The Universal Constant in Living*. These claimed to set out the plaintiff's philosophy and technique, and the defence alleged that the contents represented, in the main, testimonials and sales talk intended to advertise the teachings of his technique, but that they also contained, centring round his alleged discoveries of conscious and/or primary control, advice, claims, and statements which represented dangerous quackery.²

Case for the Plaintiff

Mr. H. J. Hansen, K.C., opening the case for Mr. Alexander, said that he had evolved a technique and ideas which had received favourable comment from such eminent persons as Sir Charles Sherrington, Mr. John Dewey, the American philosopher, Mr. Aldous Huxley, and Sir Stafford Cripps. Mr. Alexander had never pretended to be an expert physiologist, but was an educationist who had made certain observations in investigating the use and misuse of the body. In his four books he had developed the general theme that man in the course of thousands of years had developed from an unconscious creature, acting on instinct, toward a completely conscious being, that this process had been tremendously accelerated, especially in the last hundred years, and that to-day man had to rely more than ever before on a conscious reaction to his environment and the conscious use of his body. On the one hand he was to realize that there should be no conscious interference with such reflex or subconscious activities as digestion, and on the other he had consciously to understand what was the correct use and the misuse of the body, so that incorrect habits could be corrected. For instance, a man sitting for long periods at a desk would tend to hunch his shoulders and would in time come to regard that as a normal posture. To correct the error he would have to learn, on sitting down, consciously to resist the tendency to hunch the shoulders, and then consciously to obey instructions to assume a correct posture.

Dr. Jokl, one of the defendants, had met a teacher of the Alexander technique, had made some comments on the method as taught to children at the teacher's school, and had later referred to it in an address to the South African Association for the Advancement of Science. Finally came the article in *Manpower*. The general tone of the references to Mr. Alexander was scathing and derogatory, and they implied that he was a charlatan and a quack. Mr. Alexander was 80 years old; after all arrangements had been made for him to come to Johannesburg he had had a stroke and was now unfit to travel.

Mr. Pirow then submitted that the action had not been brought within the statutory period of twelve months, but the judge declined to decide that issue first.

Personal Testimony

Dr. Wilfred Barlow, giving evidence for Mr. Alexander, said that he had qualified in medicine in 1937 and had spent an extra year at Oxford on B.A. physiology. He had hurt his shoulder at sport and suffered from repeated dislocation; through following Mr. Alexander's methods he was at last able to prevent his shoulder blade from slipping out of its socket. He had become a student and later a qualified teacher of the Alexander method. What he had seen in the clinical wards of St. Thomas's Hospital had made him realize that Mr. Alexander had made an important discovery which could help in the treatment of bad muscular co-ordination or misuse. He quoted passages from a textbook issued by the Council of Physical Therapy of the American Medical Association which he said supported Mr. Alexander's theories on the effect of faulty body mechanics on health, and from articles in the *British Medical Journal*, the *Lancet*, the *Medical Press*, and the *Journal of the American Medical Association*, all of which he said were in appreciation of Mr. Alexander's work.

Cross-examined by Mr. Pirow, he said he believed, as an ideal, Mr. Alexander's argument that physical guidance by conscious control should in time make man immune from disease. Examples of how conscious control could benefit a man's health could be multiplied indefinitely. He would advise patients suffering from acute and operable cancer or appendicitis to be operated upon, and in all cases he would recommend a course of after-care instruction in proper body mechanics to improve the patient's use of his body and promote health. Mr. Alexander did not claim to cure disease but to promote its elimination.

Dr. Dorothy Drew, a London practitioner, said that she had been injured in a car accident as a student and that during the war, owing to heavy work and responsibilities, her health had deteriorated and broken down. She had become a pupil of Mr. Alexander in London, and as a result of his lessons her sinusitis and appendix trouble had cleared up, her injured arm did not bother her any more, and she felt fully healthy.

Mr. N. E. Coaker, K.C., of Johannesburg, the next witness, said that his son, when aged four, had fallen and sustained concussion and a minor skull fracture. One leg had dragged and an arm had been affected, and he had suffered from serious mental disturbances. After a course of the Alexander technique with a Johannesburg teacher the affected leg had thickened to the same size as the other, there had been no trace of drag or uncertainty, the hand and arm had returned to normal, and the temperament was strikingly stabilized. To-day the boy was outstanding both academically and in athletics. An elder son who had suffered from continuous attacks of bronchitis had gained perfect health through a re-educative course in body mechanics, and he had himself benefited from a similar course. He had been present at a demonstration of the Alexander technique by a local teacher at which Dr. Jokl had been examined. His own knowledge of the technique had shown him that the doctor's head was pulled back; he had a great roll of flesh at the back of his neck; one shoulder was slightly dropped, and he had a "Charlie Chaplin" walk. These conditions had been demonstrated to Dr. Jokl, and after manipulation he had acknowledged the improvement. An article by Dr. Jokl had been published in the *Transvaal Educational News* side by side with another setting out the Alexander view. Later he had seen an article

¹ *Johannesburg Star*, Feb. 16.

² *Capetown Argus*, Feb. 17, 18, 19, 20, 23, 24, 25 and 26.

submitted by Dr. Jokl for publication in the *South African Scientific Journal* and had complained to the publications committee that it was "defamatory, untruthful, ill-informed, common, and vulgar."

In answer to cross-examination, he said that after a course in the Alexander technique his conscious use of his body and his psycho-physical condition were improved, and this had had a remedial effect on various complaints. He rejected the suggestion that the improvement might be due to faith-healing. Certain methods involving natural laws had been practised and had produced expected results. He could not agree with Mr. Alexander that prevention would be unfailing in time, but he did not think the claim outrageous.

Miss Irene Tasker, a teacher of the Alexander technique, said she was an honours graduate of Girton and had studied under Dr. Montessori. After seeing in 1916 the effects of the Alexander technique on one of her pupils, she had inquired into the method and had become an assistant to Mr. Alexander in London; she had started teaching his methods in South Africa in 1935. She would take no pupil who refused to see a doctor. She had first met Dr. Jokl in June, 1941, when he had expressed interest and asked her to lecture. About a year later he had telephoned to her saying he was a scientific inquirer and wanted to see what the technique was about, and that he had become particularly interested on hearing that Sir Stafford Cripps supported Mr. Alexander. At a later demonstration she had shown that Dr. Jokl "pulled himself down" to a seat. After one manipulation his condition had been improved, but when he had sat down again he had reverted to the old habit. He had written her a letter in which he had thanked her for the "most interesting and able demonstration" she had given, and had added, "I certainly feel that your system means a highly important contribution in the field of education in its widest sense, and am looking forward to learning more about it from you." She had later received a request from the doctor to take a course. She had asked him why, and he had replied that it was just a rhetorical question to test her reaction. She had suggested that he should see Mr. Alexander himself.

Sir Stafford Cripps's Experience

Mr. Hansen handed in evidence taken on commission in London from Dr. Whittaker, Dr. Peter McDonald, Lord Lytton, Sir Stafford Cripps, and two other doctors. Sir Stafford Cripps's evidence said that he had protested strongly to the High Commissioner for South Africa against what he considered a gross libel of himself in the article in *Manpower* published by the Union Government. Mr. Alexander's lessons had made him feel much freer in his movements and much more rested. At the end of a two-hours speech in the House made immediately after a lesson he had not felt in the least bit tired.

In cross-examination Sir Stafford said that he had adopted the Alexander technique and vegetarianism for colitis and various internal complaints. "The extraordinary thing is that when you experience it, you become perfectly convinced he is right." In re-examination he quoted from the offending article: "The best way to explain the amazing quackery is to look on it as a typical instance of group hysterо-neurosis." His own and other names were mentioned, and there was a reference to "highly intelligent persons." The general tenor was obviously that anyone associated with this Alexander teaching was either a fool or a knave.

The Earl of Lytton, formerly Governor of Bengal and for a short time Viceroy, had said on commission that a young Indian civil servant whose health had broken down had returned from England "a new man, happy and cheerful" after treatment by Mr. Alexander. He himself had consulted Mr. Alexander on account of being much run down in health and having had a chronic headache for several years. Mr. Alexander had pulled him about and generally used his hands to put him in the position in which he wanted him; then he had said, "There, that is your place in nature now. If you always keep like that, you will always feel well." Lord Lytton had felt extremely uncomfortable and misshapen in that position, but had had very much better health. Mr. Alexander had emphasized that he was not a doctor and it was not his

business to diagnose or remove complaints but to teach his pupils to make the best use of themselves. Lord Lytton had encouraged him to start a school and training centre which he was still a trustee. This concluded the case Mr. Alexander.

Views from Physiologists

Counsel for the defence read evidence taken on commission from Prof. Samson Wright, John Astor professor of physics in the University of London, who said he had made a careful and unbiased study of Alexander's books. These made assertions which if accepted would revolutionize the whole approach to medicine, but no records were given of any histories, nor of examinations of large numbers of patients or of findings based on these which would permit an impartial person to examine and judge for himself the value of the assertions. Unless Mr. Alexander could tell in detail the method he used, readers were not justified in attaching any credence to his affirmations about "deceptive sensory appreciation." Statements on the function of certain organs, such as lungs, were "just nonsense," as was a description of the chest and abdomen as resembling a stiff oblong rubber bag.

A detailed analysis of the books suggested that, possibly through lack of formal training in physiology, Mr. Alexander had not that standard of physiological knowledge which would enable one to take his affirmations on trust, and one must treat with the utmost scepticism any claims he made dealing with effects on respiration and circulation. The contention that conscious control could regulate every function of the body was quite out of keeping with what could be easily demonstrated. In this as in other claims the onus was on Alexander, seeing that his affirmations were entirely contrary to all established evidence about the degree of control of the internal organs by the mind or will, to establish his case. Until he did so the gravest scepticism was called for in accepting his conclusions.

In the special field of the physiology of physical fitness and related subjects Dr. Jokl was probably one of the leading authorities in the world, and was eminently equipped with his knowledge and investigations to comment very competently on any physiological statements made by Mr. Alexander. When Sir Charles Sherrington had actually said about Mr. Alexander's work was: "Mr. Alexander has done a service to the subject by insistently treating each act as involving the whole individual, the whole psycho-physical man." If that were so, Mr. Alexander had said in his writings, it was, in Prof. C. D. Wright's view, a very minor service; but as this thesis was combined with an immense amount of material which was entirely untrue and misleading and probably dangerous, and, taking his writings as a whole, rendered a great disservice to the community.

Sir Henry Dale's evidence, also given on commission, was that he had found in Mr. Alexander's books "no intelligent account of any scientific discovery." They struck him as a mass of pretentious verbiage, and he would call the whole thing quackery. A given paragraph was very much in keeping with the general style and tendency to vague assertion of advertisements of proprietary nostrums.

Evidence by the Defendants

Dr. E. H. Cluver, one of the three defendants, said in evidence that he had studied at Oxford under Sir Charles Sherrington and in 1919 had been appointed professor of physiology at the Rand University on Sir Charles's recommendation. He had written two standard textbooks on practical physiology and one on public health in South Africa, and had been Secretary for Public Health in 1938. In November, 1943, a Member of Parliament had drawn his attention to an alleged cure by the Alexander method which, in accordance with his practice, he considered it his duty to investigate. He had studied the book *Constructive Conscious Control* and had glanced through others. The contents had seemed to him to be nonsense which could be left alone, something that only wealthy neurotics could fall for. The statements about wrong sensory perceptions showed no knowledge of the physiological facts and a wrong conception of the physiology of the human being. Any

tudent knew that man could not consciously control all muscular activity by the Alexander technique. His reaction had been that this matter fell into the same category as the alleged cures for cancer that he received. Later, however, he had heard that it was seriously proposed that this technique should be introduced into the schools of South Africa. He had regarded this as a most shocking proposal, a very serious threat to the health of school-children, a pernicious and dangerous proposal, and he had decided that something must be done to oppose it. He had heard that Dr. Jokl had already encouraged the protagonists of the scheme, and told him that the matter was so serious that they should expose it in *Manpower*. Dr. Jokl had been most reluctant, but on being urged had eventually prepared the article as an acknowledged authority on the subject.

Cross-examined by Mr. Hansen, Dr. Cluver wrote down the name of the woman Member of Parliament who had claimed that "a pain in the back" had been cured by the Alexander method, and agreed that she was a person of considerable intelligence. He had not tried, beyond reading the books, to discover what the Alexander technique was. He understood at the general theme was that man could be given conscious control of his involuntary muscular system—"which is nonsense." If he were told that this was not Mr. Alexander's meaning, that might cause him to revise his ideas, but the statements in the books showed gross physiological misconceptions. He felt that this pernicious technique had to be exposed in a public interest. In using such epithets as "pernicious," "dangerous," and so on, he was quite dispassionate, his only object being to protect school-children. He knew of no harm caused by the technique, but there was potential harm.

The epithets "Australian actor," "Australian gym master," and "Australian immortal" were not intended as abuse but to show the background of the man who had made these amazing claims, as was right "in exposing quackery of this kind." He thought that most of the people, but not all, who supported Mr. Alexander or claimed to benefit from his technique were neurotics. He agreed that he had himself written in 1943 a non-technical book in which he had made the point that man's instincts were not adequate to cope with the change in man's physical and psychological state and environment and that education was essential, that much sickness could be averted by proper methods, and that mental or psychological adjustments often caused conditions which led to disease; and he had expressed the hope that in time most disease might be prevented. He asserted, however, that this differed very much from Mr. Alexander's concepts, which were based on quite different and physiologically quite erroneous foundations. On re-examination, he explained that his theme had been that if man's physical and psychological environment could be created to allow all the correct factors medical treatment would become largely unnecessary and men should reach a much greater age than to-day. This had not the remotest connexion with Mr. Alexander's ideas.

Dr. E. Jokl said in evidence that he had been born in Breslau in 1907, had come to South Africa in 1933, and had been pour and manpower adviser to the Industrial Development Corporation. Since 1941 he had been a member of the National Advisory Council for Physical Education to the Union Government. He had been engaged in physical education research for over twenty years. When he had asked Miss Tasker to show him her methods he had been head of the Department of Physical Education for the Rand Technical College and had approached anyone who he thought might contribute to its studies. He had not been impressed with the demonstration and had never suggested that he was impressed. Later Miss Tasker had indicated that she could not give him lessons. As a scientific inquirer he had considered this curious and so had begun to read Mr. Alexander's books. He had felt it necessary to reply to an address on the Alexander technique given by a school inspector and later published in the Press. The content of the articles for the Alexander method had been that experts should now either accept or reject it. The challenge had been thrown out and he had accepted it. After criticisms of his *Manpower* article had appeared he had gone to England, where he had found that all the "top-notchers" in medicine

were interested, and he had been inundated with offers of evidence in support of his statements about the technique. Sir Charles Sherrington had personally introduced him to Sir Henry Dale. Asked about Sir Stafford Cripps, he replied that colitis was "one of the notorious diseases which react in many people to suggestion treatment, faith cures, hocus-pocus."

Counsel put to Dr. Jokl a letter written by Sir Charles to Mr. Alexander in which the sentences occurred: "... I appreciate the value of your teaching and observations. ... I know some of the difficulties which attach to putting your ideas across to those less versed in the study than yourself. Your disciples, however, can more and more disseminate them and multiply your call." After hearing of the publication of this private letter, Sir Charles had been disgusted and had told him he considered Mr. Alexander "a dangerous quack." The letter was one of conventional kindness, as had been his own letter to Miss Tasker. He had genuinely desired to have lessons from her to learn more about the method. He agreed, however, that letters written by him in 1943 included a bitter attack on Miss Tasker and a statement that he wished "to expose the Alexander technique and attack the racket." Most of the Alexander supporters were neurotics. They were all very clever people and there was nothing wrong with their intellect, but their emotional make-up was maladjusted. He quoted many passages from Mr. Alexander's books to support his contention that Mr. Alexander's "unqualified claims" included conscious control of the viscera. Re-examined, he said he had no quarrel with Mr. Alexander's claim to improve posture but with his claim that a particular method of attaining posture would ensure "unfailing health—curative, preventive, and promotive."

This completed the evidence for the defence, and counsel then addressed the Court.

(To be concluded)

Medical Notes in Parliament

National Assistance Bill

When the Report stage of the National Assistance Bill was taken in the House of Commons on March 5 Mr. JOHN EDWARDS moved to amend Clause 5 (Determination of Need for Assistance) by leaving out the words "pulmonary tuberculosis" and inserting "tuberculosis of the respiratory system." He said it was proposed to alter the wording to ensure that the Clause covered all infective forms of the disease.

Mr. SOMERVILLE HASTINGS asked what would happen in the case of a man who was discovered to be suffering from tuberculosis of the lungs after he had become so ill that he had had to leave his work. In that case he would not suffer loss of income by entering a hospital or sanatorium.

Mr. JAMES GRIFFITHS said the Ministry of National Insurance would prepare regulations to meet the kind of case referred to by Mr. Hastings.

The amendment was accepted, and on the motion that Clause 5 stand part of the Bill Mr. GRIFFITHS said that under this Clause the Board would be under an obligation to make special regulations in regard to blind persons and those suffering from tuberculosis of the respiratory system. The Clause as amended was ordered to stand part of the Bill. Amendments were made in further Clauses and the Bill was reported to the House.

Mr. STEELE moved that the Bill be read a third time. He took the opportunity to give an assurance that the National Assistance Board would include someone from Scotland and someone from Wales.

Mr. SOMERVILLE HASTINGS said that under the Bill one class of people would suffer. They were the district medical officers who administered medical assistance under the Poor Law. These officers were not in the true sense part-time officers. Although they were not employed whole-time they gave a twenty-four-hour service. Moreover, they were called "Senior Poor Law Officers" and could not be discharged by a local authority except with the consent of the Ministry. As they were permanent officers he asked Mr. Griffiths to be sure that justice was done to them in the grant of compensation.

Mr. JOHN EDWARDS, replying for the Government, did not take up the point raised by Mr. Hastings. The Bill was read a third time without a division.

Educational Psychology

On March 4 Mr. C. W. DUMPLETON drew attention to the Ministry of Education's Circular No. 146, which dealt with educationally subnormal children and with the selection and approval of medical officers in connexion with the certification of children and the determination of educability. The circular provided, under the heading of "Intelligence-testing for statutory ascertainment and reporting," that the authorities were required to consider the advice of their approved medical officers. In accordance with a previous clause of the circular an approved medical officer was one who had taken a course under the London University Extension and Tutorial Classes Council in conjunction with the National Association of Mental Health. This course was one of only three weeks. It was laid down that the form incorporating the advice of the medical officer must be completed entirely by him and that no part of the examination must be made or recorded by any other officer of the authority. This seemed to Mr. Dumbleton to brush aside the services of the educational psychologist and to deny to medical officers the right which medical men in other situations always had of calling in the aid of the specialist. Educational psychologists had to undergo years of training and were trained in educational work as well as in psychology. He suggested that a legal certificate could be signed by the medical officer and that the educational psychologist could still make an examination and fill up a separate form.

Mr. HARDMAN, replying for the Ministry of Education, said that the Ministry did not desire to belittle the work or status of educational psychologists nor to ignore their help in dealing with the educationally subnormal child. The paragraph in Circular 149 which said that the form must be completed in its entirety by the doctor made it difficult to use to the full the educational psychologist in the ascertainment of subnormal pupils. Because of that the Ministry would agree to amend this rule in such a way as to make it clear that the educational psychologist could play his full part. This would entail some revision of the statutory medical report form. Mr. Tomlinson was prepared to consult the Advisory Committee on handicapped children about this revision. At the same time the House had to remember that the law required a medical report, and this meant a report from a qualified doctor. The Courts would only recognize such a report, and to prepare it the doctor must make a mental and physical examination of the child. He must study its behaviour systematically as well as summarizing its general reaction. The intelligence test could be carried out by an educational psychologist who would accompany his record with comments in order to assist the reporting doctors. He agreed that for the majority of retarded children the educational problem was the primarily important one and that educational psychologists in co-operation with teachers were better equipped than doctors to diagnose the trouble and prescribe the treatment. At the same time the Ministry had to remember the right of the parents to appeal to the Minister, and it would be improper to take formal action without making a report which could be laid before the Minister. A way could be found by administrative action of utilizing the abilities of the educational psychologist.

Medical Manpower

When the Army Estimates were discussed on March 9 Dr. HADEN GUEST spoke of the atom bomb, bacteriological warfare, and new forms of chemical warfare. He hoped the House would discuss these subjects in a civil defence debate or on some special occasion. The atom bomb was expensive to produce, but bacteriological warfare was cheap. The resources of a good county public health laboratory were sufficient for manufacturing the deadliest germ weapons. The association between civil and military organizations would consequently have to be much closer. The problem as it applied to medical officers in the Services was an example of the difficulties to be faced. At present there was great difficulty in supplying the full quota of medical specialists to the Army and a lesser difficulty in the other Services. The difficulty would be greater in 1949 because from the beginning of that year the period of service would be one year only and it would be, for practical purposes, impossible to make the services of these officers available in distant theatres. As a rule the medical officer of an age which made him subject to calling up had not had time in which to take the higher specialist qualifications. The National Service Act allowed the service of specialists to be deferred to a later age, but in effect the specialist who was called up would be a junior specialist. They could not expect the man under thirty to be capable of acting as consultant medical officer. Yet it was upon highly placed consultant officers that the efficiency of the medical service

would depend. The difficulty was increased by the demand made on medical manpower in other fields. When the National Health Service Act came into operation it would demand an immediate increase in the number of specialists in many areas of this country and shortly afterwards would also demand an increase in the number of general practitioners. Demand were also rightly made on medical manpower for the Colonial Service. It had been necessary to make a special arrangement in West Africa and in another colony by which medical men recruited for what would normally have been military duty were allocated to service in the Colonies and that service was accepted as discharge of their military obligation. The expansion of civil defence which had been announced would be another large drain on medical manpower. Dr. Guest trusted that co-ordination of common services within the Forces could be carried out immediately. There was no sense in the medical services of the Navy, Army, and Air Force having different kinds of forms on which to report the same kind of disability. They should have the same forms and in their administration the same rules. The demands of the services for specialists and administrative officers could be met only by creating a large number of regular commissions or of short-term commissions for five years. Unification of the medical services of the three Services would bring an economy of medical personnel by between 5 and 10%. The three medical services co-operated in Malta and worked together in Hong Kong and other areas. During the war most of the hospitalization of casualties was carried out by the Army whether the casualties were from the Navy, the Army, the Air Force, or were civilians. He trusted that the whole of the medical services would be co-ordinated into one to include the National Health Service, general and special services, and also the Army, Navy, Air Force, and Colonial Services.

During the war the medical base for the treatment of casualties was largely in the hands of the Emergency Medical Service, a civilian organization whose good work had not yet been fully recognized. A unified medical service would make it possible for superannuation schemes to be interchangeable between one branch and another. It would give every medical man or woman a wider opportunity of choosing a career. This practical proposal had been discussed by many medical and military authorities. The same considerations applied in large measure to scientific and technical services of other kinds.

Replying to the debate Mr. STEWART said Dr. Haden Guest had a special knowledge of the medical services in the Army. Mr. Stewart admitted that there was a shortage of specialists and said it was difficult to see an immediate remedy. The Army was by no means the only sufferer. It was important to make the best use of the specialists which the Army possessed. An investigation in which Dr. Haden Guest had shared had concluded that the Army Council was acting rightly in that respect. As Dr. Guest suggested, further economies were possible by co-ordination between the medical services of the three defence Services. A recently appointed committee was working on that problem. Mr. Stewart hoped that it would help to provide a solution.

Improvised Health Centres

Sir ERNEST GRAHAM-LITTLE asked on March 9 whether Mr. BEVAN knew that the East Sussex County Council proposed to improvise health centres out of premises originally provided as maternity and child welfare clinics.

Mr. BEVAN said there was no question of improvisation. The County Council proposed to continue to use the premises for the maternity and child welfare service. He had no evidence that they were unsuitable for that purpose.

On March 10 Sir ERNEST GRAHAM-LITTLE asked Mr. BEVAN if, in issuing his final invitation to individual doctors to join the new Health Service, he would make it clear, especially to general practitioners, that the provision of health centres was indefinitely postponed, and that with that postponement it would be impossible to supply the facilities for carrying out the numerous services detailed in Section 21, with the result that the young doctor commencing medical practice would have to find for himself the equipment necessary, by the appointed day.

Mr. BEVAN referred to the answer given on Feb. 10 to a previous question by Sir Ernest Graham-Little (*Journal*, Feb. 28, p. 421).

Hospitals Taken Over.—Mr. BEVAN informed Mr. Linstead on March 11 that he had advised all hospitals which appeared to him liable to be taken over. He added that he was deciding, with the help of the Regional Boards, which hospitals it would be proper to disclaim.

Grants for Medical Students.—On March 11 Mr. TOMLINSON told Dr. Santo Jeger that at present 2,540 grants from the Ministry of Education for medical students were in force. Of these, 2,539 provided for the payment of full fees and a maintenance grant, 6 for a maintenance grant only, 3 for full fees only, and 22 for part fees only. Local Education Authorities also gave grants to medical students, but figures for these were not available.

Mental Hospital Officers.—Mr. HRYAN told Mr. Dumbleton on March 11 that he would not amend Regulation 29, in respect of mental health officers under the National Health Service Act, so as to give the same treatment to all mental health officers with regard to their previous service. Mr. Dumbleton alleged discrimination between staff of the Mental Hospital Service and the Certified Institution Service. Mr. HRYAN added that he was considering whether it would be possible to amend the basis as regards the officers of mental deficiency institutions to enable them to get a just measure of benefit in respect of their future service.

Extra Rations for Invalids.—Asked on March 11 why the Minister of Food had refused to grant additional rations to a boy whose own medical adviser had given a certificate that the boy had intermittently suffered from asthma for seven years, Mr. SUMMERSKILL said the Ministry's medical advisers never undertook to examine applicants for special rations, but always accepted the diagnosis of the patient's own medical adviser. Their unwelcome task was to advise on the relative needs of different groups of invalids bearing in mind the limited amounts of rationed food available. The need of uncomplicated cases of asthma for extra rations was not such as to justify a claim on this limited supply.

Universities and Colleges

UNIVERSITY OF OXFORD

In a Congregation held on Feb. 28 the degree of H.M. was conferred on Elizabeth A. Heyan John.

UNIVERSITY OF CAMBRIDGE

The following medical degrees were conferred on Feb. 28:

M.D.—G. B. French, C. P. Peck, W. H. H. Jobb, G. M. Barrett, J. W. Bromley,
J. N. Horne, W. Warren.
M.B., B.Ch.—R. C. Roxburgh, *H. B. Griffiths, *J. P. D. Thomas, *P. G.
Sommers, A. H. Jones.

UNIVERSITY OF DUBLIN

SCHOOL OF PHYSIC, TRINITY COLLEGE

The following medical degrees were conferred on March 16:

M.H., B.Ch., B.A.O.—W. B. Alcott, Brenda M. Charley, J. V. Connolly, Sheila Davies, G. W. Keating, J. D. Kentley, J. W. McCaw K. McIntyre, M. Marcus, D. J. J. Waugh.

UNIVERSITY OF LONDON

The examinations for the M.H., H.S. degrees in October, 1948, April, 1949, and October, 1951, will start one week later than the date laid down in the Regulations, provided the necessary accommodations are available.

For examinations in and after 1949 the external and general internal first examinations for medical degrees will be held one week earlier—i.e., beginning the last Monday in June.

UNIVERSITY OF MANCHESTER

The Council of the University has accepted a gift of £1,000 made by Mrs. Lapage to establish in memory of her husband, the late Dr. C. Paget Lapage, a prize which will be offered annually for ward on the paediatrics section of the final examination for the degrees of M.B., Ch.B. Dr. Lapage, who was a graduate of the University and a member of the University Court, was for many years on the staff, being since 1934 Reader in the Diseases of Children.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

The Royal College of Physicians of London has arranged a course of postgraduate lectures in medicine to be given from May 3 to June 25, at 5 p.m. There will be approximately 26 lectures. The full programme is not yet complete but preliminary details can be obtained from the College (Hall Mall East, London, S.W.1). The exclusive fee for the course is £7 7s, and the total entry will be limited to 200. Fees are payable in advance and must be received by April 19.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

At an ordinary meeting of the Council of the College, held on March 11, with Sir Alfred Webb-Johnson, Bt., President, in the chair, Mr. C. Gill-Carey, Mr. J. P. McMurray, and Mr. S. A. J. Malkin were elected Fellows of the College. The appointment of Sir John Anderson, F.R.S., and Sir Henry Dole, F.R.S., as Trustees of the Hunterian Collection was reported. Dr. A. D. Martin was elected the first Dean of the Faculty of Anatomists in the College. A Hunterian Professorship was awarded to Dr. Shohl, Shd. by, a Cura.

The following hospitals were recognized in respect of the special surgical posts required of candidates for the final Fellowship examination: Royal Infirmary, Gillingham (resident consultant surgical officer); St Luke's Hospital, Guildford (senior house-officer); Ayricham General Hospital (resident surgical officer for a period of two years in the first instance); Royal Northern Infirmary, Inverness (recognition now to be made permanent).

Diplomas of Fellowship were granted to the following candidates:

G. B. C. Penfield, A. D. Meecey, E. McK. Crisp, P. J. Barford, H. H. Reynolds, N. S. Slater, D. H. G. Waller, W. H. Potts, G. S. Lunt, J. H. Barker, W. A. Hamner, R. J. Jones, A. I. Wall, A. H. Dunn, G. F. Brown, W. S. G. S. Sims, I. D. Austin, H. A. Bailey, A. A. Scott, A. H. Lee, C. T. F. Gardner, C. McCulloch, W. Langley, J. A. G. Rees, A. P. Vignani, E. Fleming, M. E. Hall, G. R. Langford, J. A. G. Rees, A. P. Vignani, H. Bolton, D. H. Duffy, V. O. Walden, R. H. Wetherill, P. H. Williams, J. W. Mackay, A. V. Pollock, A. J. F. Braden, D. D. Bennett.

A diploma of Membership was granted to S. Raza

A Diploma in Public Health was granted, jointly with the Royal College of Physicians of London, to A. W. Meade.

SCOTTISH COUNCIL BOARD

The following candidates, having passed the final examination, have been granted the diploma of I.R.C.P.(d), I.P.C.(d):
I.R.P.P.&S Class: G. G. Allan, S. J. Alexander, A. J. Barr, Mrs. H. Bruce, G. Cameron-Mowat, Margaret C. B. De la Motte, Mrs. A. Hamilton, G. J. C. Hird, S. Hopland, Mrs. A. H. J. P. Kelly, C. Kopet, J. F. Lee, J. D. C. Lyons, J. M. C. (Ber.) J. McKee, Birkie, Mary C. MacKer, Jeanne G. Marshall, Pamela J. B. Power, Catherine J. A. Robertson, S. S. Ross, J. S. Ross, J. P. Thompson, J. E. H. Tullie, W. F. Watson, H. Weiss, B. Williams.

The Services

Surgeon Lieutenant-Commanders G. F. M. Bennett and G. L. Foss, R.N.V.R., have been awarded the R.N.V.R. Decoration.

Air Vice-Marshal P. C. Livingston, CBE, CBE, AIC, has been appointed Director-General of Royal Air Force Medical Services in succession to Air Marshal Sir Andrew Green, FRCGS, CBE.

AUXILIARY ROYAL ARMY MEDICAL CORPS, 1902.

The annual general meeting of the members of the Auxiliary Royal Army Medical Corps Funds will be held at 11, Grosvenor Street, London, W., on Monday, April 2, at 4.30 p.m., when the report and accounts for 1937 will be presented and the new auditors elected for 1938.

DEATHS IN MIL. SERVICES

Squadron-Leader *Micahel, John Cameron*, died in hospital on Feb. 20. He was born in July, 1922, and was a student at Glasgow University. He graduated M.B., Ch.B. in 1943 and worked as house-surgeon at the Royal Maternity Hospital, Glasgow. He was then commissioned in the Royal Army Medical Corps, where he served until August, 1949, when he transferred to the Medical Branch of the Royal Air Force. On taking a leave of absence, his commission in 1954 he was appointed and on his return to the London Recruiting Depot of the Royal Air Force. In the interim he continued to serve until June, 1950, when he was appointed a commission as flight-lieutenant in the R.A.F.V.R. He was promoted to the rank of squadron-leader in January, 1955, and in recent years had been employed in the country on medical board duties.

The National Baby Welfare Council (29, Gordon Square, London, W.C.2) has issued a pamphlet entitled *Infant and Personal Hygiene*. It is obtainable from the Council for 1d. and 11 postage. Simple diagrams illustrate the exercises, and notes attempt to explain how and when they should be carried out.

No. 9

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Feb. 28.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1948					1947 (Corresponding Week)

Rate per 1,000 total births (including stillborn)	—	—	31	—	—	—	—	34	—	—

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

|| Includes puerperal fever for England and Wales and Eire.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In *England and Wales* a rise occurred in the incidence of whooping-cough 79 and measles 103, while decreases were recorded for scarlet fever 118, acute pneumonia 56, and dysentery 46.

The largest rises in the notifications of measles were: London 166, Northamptonshire 137, and Middlesex 99; the largest falls were Lincolnshire 99 and Monmouthshire 92. The only large variation in the returns for whooping-cough was an increase of 100 in Yorkshire West Riding, an increase which was spread over the whole county.

Decreases in the incidence of scarlet fever were reported in Middlesex 38, London 37, Norfolk 30, and Glamorganshire 26; the only large rise was that of Yorkshire West Riding 50. No change of any size occurred in the local trends of diphtheria. A small fall in the incidence of acute pneumonia was recorded in every region except that of the south Midlands, where there was a slight increase.

The largest returns of dysentery were: Lancashire 41 (Blackpool C.B. 12), Yorkshire West Riding 38 (Bradford C.B. 10, Sheffield C.B. 19), and London 12. Only three counties had more than one notification of acute poliomyelitis—Middlesex 5 (Heston and Isleworth M.B. 3), London 5, and Sussex 3 (Cuckfield R.D. 2).

In *Scotland* a decreased incidence was recorded for measles 116 and for diphtheria 21, and an increased incidence was reported for acute primary pneumonia 52 and scarlet fever 30. The fall in the incidence of diphtheria was due to a decrease throughout the western area. Notifications of dysentery declined in the north-eastern area but rose in Edinburgh and Glasgow, where 23 and 17 cases, respectively, were notified during the week.

In *Eire* an increase in the notifications of measles 54 and decreases in scarlet fever 18 and whooping-cough 18 were reported. The rise in the incidence of measles was contributed by three areas—Donegal (Donegal R.D. 31), Dublin (Dublin North R.D. 13), and Galway (Galway R.D. 14). Of the 15 cases of typhoid 10 were notified in Louth, Dundalk U.D.

In *Northern Ireland* increases were reported in the notifications of measles 16, scarlet fever 10, and whooping-cough 6. These rises were due to the experience of Belfast C.B.

Travellers to Saudi Arabia

The Epidemiological Bureau at Alexandria states that the Kingdom of Hedjaz no longer requires anti-cholera inoculation certificates from travellers coming from Egypt.

Week Ending March 6

The notifications of infectious diseases for England and Wales during the week included: scarlet fever 2,069, whooping-cough 3,067, diphtheria 200, measles 8,788, acute pneumonia 794, cerebrospinal fever 42, acute poliomyelitis 22, dysentery 184, paratyphoid 2, and typhoid 5.

Medical News

Medical Society of London

The 168th Anniversary Dinner of the Society was held on March 11 at Claridge's Hotel, London, with the President, Mr. W. E. Tanner, F.R.C.S., in the Chair. The toast of the Society was proposed by the Marquis of Reading and responded to by the President, who observed that the Society had among its members all sections of the medical profession. Whatever might happen with the National Health Service Act, Mr. Tanner said, the voluntary principle would never disappear. The health of the guests was proposed by Mr. G. Armitage, F.R.C.S., and responded to in a characteristically witty speech by Sir Alfred Webb-Johnson. Sir Alfred observed that we were living in times when the freedom of the professions was in danger. The medical profession happened to be the first in the assault. He referred to the supremacy of the law over the executive as the palladium of our liberties and said that the freedom of the profession was involved in the freedom of the peoples.

Lecturing in Poland and Czechoslovakia

Dr. E. A. Carmichael, Director of the M.R.C. Neurological Research Unit, is lecturing in Poland until March 31 and then going for a week each to Czechoslovakia and Austria on behalf of the British Council. He is speaking on the dynamics of the cerebrospinal fluid in man, fatigue and impairment of muscle function in man, and epilepsy.

Ophthalmological Society Award

The Council of the Ophthalmological Society of the United Kingdom has awarded the Treacher Collins Prize to Hugh S. Stannus, M.D., Ph.D., F.R.C.P., for an essay on nutritional eye disease.

Irish Honours for European Scientists

Dr. Gunnar Dahlberg, professor of human genetics in the University of Uppsala, and director of the Swedish State Institute of Human Genetics and Race Biology, has been appointed honorary director of the Lomeshie Research Centre for Anthropology and Race Biology at Londonderry. Dr. Ernst Krueger, an authority on tropical diseases, has been elected an honorary consultant and adviser to Section C (Medicine) of the centre.

Yellow Fever Inoculation at Dundee

Inoculation against yellow fever may be obtained free of charge at the Bacteriological Department, University of St. Andrew's, 60, Small's Wynd, Dundee. Applications (preferably in writing) should be made to Prof. W. J. Tulloch at that address. Sessions are normally held on Mondays, at 2 p.m.

Vaccination

A memorandum on vaccination against smallpox issued by the Ministry of Health recently is being distributed to public vaccinators. It recommends the "multiple pressure" technique which has been in general use for some years in the United States. Copies may be obtained from H.M. Stationery Office, price 2d. or post-free 3d.

Wills

Dr. Charles Bolton, C.B.E., F.R.S., who was director of pathological studies and research at University College Hospital, left £50,880. Dr. Arthur Willoughby Tibbitts, of Pedmore, Worcs, left £25,987. Dr. Charles James Boucher, of Co. Down, left £3,544. Dr. John Evans, of Walton-on-Thames, Surrey, left £16,058.

COMING EVENTS

Honyman Gillespie Lectures

A series of Honyman Gillespie Lectures has been arranged, in association with the Edinburgh Postgraduate Courses, to be held in the West Medical Theatre, Edinburgh Royal Infirmary, on Thursdays at 4.30 p.m. from April 15 to May 27. Details will be published in the diary column of the *Journal* week by week. The lectures are open to all graduates and senior students.

Contraception

A practical demonstration of contraceptive methods will be given by Dr. Marie Stopes and Dr. Beddow Bayly on Thursday, April 1, at 2.30 p.m. Medical practitioners should apply for tickets well in advance to 108, Whitfield Street, London, W.1.

Edinburgh Lectures

In connexion with the postgraduate courses in medicine and surgery a series of open lectures on subjects of wide biological interest has been arranged by the Edinburgh Postgraduate Board for medicine to be given in the West Medical Lecture Theatre of the Royal Infirmary on Tuesdays, April 20, May 4 and 25, and June 15 and 29, at 5 p.m. All graduates and students are invited to attend. Details will be published in the diary column of the *Journal* for the appropriate weeks.

Health Congress at Harrogate

Lord Inman has accepted office as president of the Health Congress of the Royal Sanitary Institute, which is to be held at Harrogate from May 24 to 28. Eight sections have been arranged for the congress, as follows: preventive medicine; engineering and architecture; maternal and child health; veterinary hygiene; food and nutrition; housing and town planning; tropical hygiene; and hygiene in industry. In addition there will be conferences of medical officers of health, engineers and surveyors, sanitary inspectors, and health visitors. The following members of the medical profession are among the presidents of sections and conferences: Prof. G. S. Wilson, Prof. P. A. Buxton, F.R.S., Prof. Andrew Topping, Prof. R. E. Lane, and Dr. F. Hall. The food and nutrition section of the congress will be held jointly with the Food Group of the Society of Chemical Industry, whose chairman, Dr. E. B. Hughes, will act as president of the joint meeting. The programmes for the sections and conferences are nearing completion and details will be issued later by the institute (90, Buckingham Palace Road, London, S.W.1).

Industrial Medicine

The Institute for Occupational Health of the Long Island College of Medicine is presenting a postgraduate course in Industrial Medicine from April 5 to 16. The fee is 75 dollars. Inquiries should be addressed to Dr. Thomas D. Dublin, Department of Preventive Medicine and Community Health, 248, Baltic Street, Brooklyn 2, New York.

SOCIETIES AND LECTURES

Saturday

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES. 11, Chandos Street, London, W.—March 20, 2.30 p.m. General meeting. "Venereal Affections of the Eye," by Mr. R. Lindsay-Rea.

Monday

MENTAL AFTER CARE ASSOCIATION.—At Burlington House, Piccadilly, London, W.—March 22, 4 p.m. Annual meeting. Address by the Rt. Hon. Mr. Justice Birkett, P.C. The annual report will be presented by Dr. Henry Yellowlees, chairman of the association.

Tuesday

UNIVERSITY COLLEGE LONDON: DEPARTMENT OF PHYSIOLOGY, Gower Street, W.C.—March 23, 5 p.m. "Some Aspects of General Physiology," by L. E. Bayliss, Ph.D.

Wednesday

EGYPTIAN EDUCATION BUREAU.—At 4, Chesterfield Gardens, Chester Street, London, W.—March 24, 6 p.m. "Some Observations on the Surgery of Peripheral Vascular Disease," by Prof. A. M. Boyd.

ROYAL MICROSCOPICAL SOCIETY.—At B.M.A. House, Tavistock Square, London, W.C.—March 24, 5.30 p.m. for 6 p.m. "Studies of Industrial Microscopy. 'The Microscopy of Food,'" by Mr. H. L. Shipp, B.Sc., A.R.I.C.

SOCIETY OF CHEMICAL INDUSTRY: FOOD GROUP.—At Burlington House, Piccadilly, London, W.—March 24, 6 p.m. Joint meeting of Nutrition Panel and British Dietetic Association. "Special Dietary Requirements in Sickness and Convalescence," by Dr. D. P. Cuthbertson and Miss P. M. Simmonds, S.R.N.

APPOINTMENTS

BOWMAN, A. K., M.B., Ch.B., Senior Administrative Medical Officer, South Western Regional Hospital Board.

DEWAR, ROBERT S., M.D., D.P.H., Resident Physician Superintendent, Communicable Diseases Hospital, Maitland.

DONN, R. M., B.Sc., Medical Director, Mary Eddowes Hospital, Northumberland County Council.

MANCHESTER ROYAL INFIRMARY: Honorary Assistant Physician (with special interest in Neurology): G. E. Smyth, M.D., F.R.C.P. Honorary Assistant Physicians: H. T. Howat, M.R.C.P., and A. Morgan Jones, M.R.C.P.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Arthur.—On March 3, 1948, at Port Stanley, Falmouth District, to Philip (née Hayward), wife of G. D. Arthur, M.R.C.S., L.R.C.P., Colonial Medical Service, a son.

Ferguson.—On Feb. 18, 1948, at Clonsilla Nursing Home, to Dr. and Mrs. Alan Ferguson (née Kathleen Smyth) 11, North Park Drive, 1 Clonsilla, a son.

Oldham.—On Feb. 27, 1948, at Maternity Unit, Cammerton Infirmary, to Valerie (née Williams), wife of William Oldham, M.B., Ch.B., a daughter.

Welch.—On March 5, 1948, at Elton House, Dean Road, South St. 10, to Dr. and Mrs. H. D. Welch, a son.

MARRIAGE

Parker-Davies.—On Feb. 29, 1948, at St. Peter's, North St. 10, W. 1, to Shepherd Parker, M.B., Ch.B., D.P.H., at Maitland, Dean Road, South St. 10, Ch.B., D.P.H.

DEATHS

Atkinson.—On March 2, 1948, at Queen Mary's Hospital, Roehampton, to Alexander Atkinson, M.B., Ch.B., of 19, Rhinoceros Gardens, Forest Hill, S.W.

Dawson.—On March 4, 1948, at 27, Queen's Road, Bromley, Kent, to Alice Dawson, M.D.

Hallam.—On March 4, 1948, at St. Martin's, Broadwater, Falmouth, M.B., Ch.B., aged 60.

Hamilton.—On March 5, 1948, at Eastwood, Bude, Dorset, to Mrs. L.S.A., aged 61.

Heiser.—On March 4, 1948, at 3, D. de la Paille, St. Leonards-on-Sea, to Lewis Heiser, M.R.C.S., L.R.C.P., late of C. 1947, a son.

Hird.—On March 2, 1948, at Trevelyan, Somerset Road, Epsom, Surrey, to Robert Hird, Doreen Hird, M.D., F.R.C.S. Ed., aged 60.

Jeans.—On March 1, 1948, at Edinburgh, George Lane, M.P., C.I., and McNeill.—On March 3, 1948, at 44, Half Moon Lane, Hammersmith, S.W. 6, to Hugh McNeill, M.D., aged 61.

Middlebrook.—On March 2, 1948, at Daphne, Brompton, Park, Chesham, Chesham, Herbert Edwin M. Middlebrook, M.B., Ch.B., D.P.H., aged 40, husband of Mary Evelyn Middlebrook.

Phillips.—On March 1, 1948, at West London Infirmary, Gt. George Street, to John Phillips, M.D., aged 60.

Ravall.—On March 7, 1948, at Great London, Cavendish Square, London, M.D., aged 64.

Speck.—On March 6, 1948, at 30, Speck, M.R.C.S., L.R.C.P., aged 60, at Lambeth Road, London, S.W., aged 64.

Syme.—On March 2, 1948, William James Syme, M.B., Ch.B., 114, Gower Avenue, Eastwood, Surrey.

Thomson.—On March 1, 1948, at The Park, 10, Park, Maitland, to Duncan Thomson, M.B., Ch.B.

Wade-Evans.—On March 2, 1948, at South London Hospital, Guy's, Common, S.W., Elizabeth Patricia Wade-Evans, M.B., Ch.B., of Guy's Hill Hospital, Colchester, Surrey.

White.—On March 3, 1948, at a Graveland, 10, Graveland, to Ott White, M.R.C.S., L.R.C.P., D.M.R.E., aged 60.

Williams.—On March 3, 1948, at 10, 10, 10, Williams, M.B., Ch.B., M.R.C.S., L.R.C.P., aged 60.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Recurrent Attacks of Lobar Pneumonia

Q.—Can anything be done to prevent children who have recovered from a first attack of lobar pneumonia developing fresh attacks at intervals of a few months?

A.—It is possible in such cases that resolution has not been complete, or that the pneumonia was associated with the blocking of a bronchus and collapse of a portion of the lung. X-ray studies indicate that the latter explanation is the more probable, and "unresolved pneumonia" is being less used nowadays as a term in children's work. In either case, a change of air, breathing exercises, and letting the child run about and expand the lungs fully will all help, and, indeed, many children with collapse of the lung get perfectly well on this programme. If radiographs show that a collapse is persisting, then the question of further measures to induce re-expansion arises. These would include postural drainage, "slapping" the chest in a more intensive attack by physiotherapy, and possibly the use of iodides to promote pulmonary secretion. If these measures fail, then bronchoscopy should be undertaken, with or without previous bronchography.

Since the question says "recovered," it may be assumed as a second alternative that no apparent pathological change persists as proved by x-ray study. In this case measures to raise general and specific immunity should be considered. The state of the child's upper respiratory tract, especially the nasal sinuses, should be investigated and any disease process dealt with. Finally, the epidemiology of the recurrent attacks might be considered. Is there a "carrier" in the house or school?

Achondroplasia

Q.—Can you give me particulars about achondroplasia, or, as some call it, chondrodystrophy? Is it related to dwarfism in certain animals, such as the conditions we find in the Ancon sheep and the dachshund? It is generally considered to be a Mendelian dominant: is that so? Does it affect the sexes equally? Can it be traced to an endocrine deficiency?

A.—The essential pathological feature of achondroplasia is a disturbance of endochondral ossification, especially at the ends of the long bones. There is not a failure of development of the cartilage, as the name might imply, but an arrest of bone formation in cartilage. Bones formed in membrane are little if at all affected. Clinically, therefore, the most striking manifestations are present in the long bones and base of the skull. The spine is also affected, though to a less extent. Certain animals have characteristics which are thought to be related to achondroplasia, but there are many aspects of the problem that are not fully understood. Thus in the dachshund the limbs are achondroplastic but not the head; while in the pug-dog the reverse is the case. Matings of pure-bred Dexter cattle (a diminutive breed) result in a high proportion of non-viable monsters having skeletal changes closely resembling those of achondroplasia.

In the case of the Dexter cattle referred to above the incidence of the achondroplastic condition suggests that it is a Mendelian dominant character. The same is probably true of the human disorder. It is interesting to note that attempts made by Catherine de' Medici to raise a race of achondroplastic dwarfs by arranging their intermarriage were unsuccessful. This may have been largely due to the fact that spontaneous delivery of a living child by an achondroplastic woman is often impossible owing to the extreme narrowing of the pelvic inlet. Achondroplasia affects the two sexes equally. Its cause remains unknown. It has not been traced definitely to an endocrine deficiency, and no histological changes in the endocrine glands have been consistently demonstrated. Nevertheless an

insufficiency of the anterior pituitary secretion during development is regarded by some as the most likely cause of the condition.

Diasone in Leprosy

Q.—What are the dosage, mode of action, and toxic reactions of diasone in the treatment of leprosy?

A.—The dosage of diasone in the treatment of leprosy is 0.33 g. daily for the first two weeks and then a gradual increase to 1 g. daily. It is given by mouth and may be continued for long periods. The mode of action is similar to that of sulphonamides in streptococcal infections. Diasone is a derivative of diamino-diphenyl sulphone, and is closely related to the sulphonamides, such as sulphanilamide. The toxic reactions which occur in 1-5% of those treated are increased erythema nodosum with fever, dermatitis, gastric intolerance, haematuria, anaemia, and iridocyclitis.

Stilboestrol and Dienoestrol

Q.—Is there any evidence that stilboestrol and dienioestrol may be carcinogenic? What are the dangers of taking dienioestrol for menopausal rheumatism?

A.—So far as the human being is concerned the evidence is only presumptive in nature. All oestrogens, natural or synthetic, are powerful epithelial stimulants acting especially on the tissues of the breast, uterus, Fallopian tubes, vagina, and vulva. They cause endometrial hyperplasia, and many pathologists believe that this condition can itself lead to carcinoma. Some of the natural oestrogens have a chemical formula similar in type to that of the carcinogenetic tars. In animals skin cancer has been produced by repeated local applications of oestrogens, and this hormone has been shown to favour the development of breast carcinoma in strains of mice which are not otherwise susceptible, and in male animals. However, oestrogens have never been shown to cause carcinoma in the human being, and there is probably little risk of this provided ordinary dosage is used and treatment is not continued for an indefinite period. Nevertheless there is good reason for caution when dealing with a patient who has a precancerous lesion in the genital tract (e.g., leucoplakia vulvae, chronic cervicitis) or who has a strong family history of malignant disease. For further details reference might be made to an article, "Oestrogens and Carcinoma of the Uterus," by A. A. Gemmell and T. N. A. Jeffcoate (*J. Obstet. Gynaec. Brit. Emp.*, 1939, 46, 985).

The dangers of taking dienioestrol for menopausal rheumatism depend on how much is given and for how long. The dose should not exceed 0.3 mg. daily, and should be gradually reduced with a view to completing the course of treatment in two or three months. Even with this dose uterine bleeding may occur. With uncontrolled and prolonged dosage the chief risks are endometrial hyperplasia, uterine haemorrhage which may require curettage if only to exclude other causes, and severe menopausal symptoms following sudden cessation of treatment.

Penicillin and Procaine

Q.—Can you tell me whether 3% "novutox," or any of the accessory preservative substances which this proprietary local analgesic contains, would be likely to inactivate penicillin if used as a solvent for intramuscular injection?

A.—Novutox contains procaine and iso-octylhydrocupreine hydrochloride. It is known that penicillin is not inactivated when procaine is mixed with it, but there is no information on the effect of octylhydrocupreine. The only way to determine whether novutox inactivates penicillin is to prepare mixtures and to have them assayed. It is likely that if the mixture is not alkaline the penicillin will not be inactivated. There will shortly be put on the market a compound of procaine and penicillin in oil for intramuscular injection. A new crystalline penicillin has been prepared by combining procaine with penicillin G; the crystals have a solubility of approximately 7,000 units per ml. in oil, oil-and-water emulsion, or physiological saline; they contain not less than 90% penicillin G with a potency of 940 units per mg. (1,040 units per mg. theoretical). In the oil suspension at least 50% of the total weight of the

particles are 50 μ or more in length. When intramuscular injections of procaine penicillin in cotton-seed oil were given to patients it was found that they had blood levels of 0.062 to 0.496 units per ml. after injections of 1 to 4 ml. There was no local or systemic reaction. It is suggested that the slower absorption of this form of penicillin is due to the larger size of the particles. The importance of particle size for slow absorption has been demonstrated by Dowling *et al.* (1947) and Welch *et al.* (1947). The presence of wax has been the cause of a number of local reactions. The relevant papers are: Sullivan, N. P., *et al.*, *Science*, 1948, 107, 169; Dowling, H. F., *et al.*, and Welch, H., *et al.*, Meeting of Syphilis Study Section, Washington, D.C., Sept. 24, 1947.

Breast Development

Q.—Is hormone therapy a safe method for increasing breast measurements? What is the optimum dose of oestrin and progesterone when used for this purpose?

A.—Inadequate development of the breasts may be due to general lack of endogenous oestrogen and progesterone, but more usually it is due to a local refractoriness to a normal stimulus. Therefore local innunction with oestrogens increases the concentration of stimulation at the site and may be successful. A useful ointment is one containing 2 mg. of oestradiol enzoate per g. put up in 18-g. tubes, which can be used over a 4-day period and continued for some months. Such local treatment is unlikely to prove disturbing. If progesterone is also given by injection it should be administered only in the 5 days preceding menstruation.

Scrotal Eruption

Q.—What is the most likely cause of a chronic scaly irritating eruption, confined to the scrotum, in a patient free of lthiriasis and other local causes of irritation? Is it likely to be related to athlete's foot, which coexists; and what line of treatment is suggested?

A.—The lesion described might be due to fungus, but the stains given are not sufficient to allow a serious opinion to be expressed. The only certain method of arriving at a diagnosis in this regard is by examining scrapings in liquor strassae under the microscope and attempting to culture the fungus. If the lesion is of fungus origin it should respond readily to Whitfield's ointment or dithranol ointment. The reaction may be unrelated to ringworm of the foot and may be a chronic eczematous or seborrhoeic dermatitis, in which case therapy may be most helpful.

Scrotal Hernia

Q.—Would the presence of a scrotal hernia which is more uncomfortable in the scrotum than when held in the abdomen by truss cause sterility in the affected testicle by the continued, though slight, pressure and by the increased temperature of the bowel loop adjacent to that organ?

A.—Theoretically, the testicle on the affected side would be subject to increased warmth and pressure, but its fertility would not be likely to be seriously impaired. In any case the testicle on the opposite side would not be affected, and an occasional men analysis would be a more reliable guide than theoretical considerations.

Assessment of Disability

Q.—What is the percentage disability allowed in the case of labourer for the loss of (1) thumb, (2) index, (3) middle, (4) ring, and (5) small finger, right hand? It is assumed that the scar is on the dorsal aspect and that the amputation is full or partial. Is there any way of finding out if the scar is painful, other than taking the patient's word for it?

A.—The problem of compensation in cases of hand injury is somewhat complicated because of the number of factors that must be taken into consideration. Apart from the nature of the man's occupation, important factors are age, whether the major or the minor hand is affected, and whether or not there is pain or tenderness. An award for permanent disability is based on decreased earning power, and is intended to help the support of the patient and his dependants until he has

adapted himself to his new environment. Strictly, it is not compensation for loss of a part, though it may be assessed on the basis of loss of parts.

An average disability assessment in the case of a general labourer for loss of digits would be: thumb, 15%; index finger, 8%; middle finger, 6.5%; ring finger, 5%; little finger, 3.5%. There is no satisfactory objective test to determine whether or not a scar is painful.

Iritis and Ulcerative Colitis

Q.—Is there any connexion between ulcerative colitis and iritis? A female patient has suffered from ulcerative colitis for the past 18 months; about 12 months ago she developed an acute iritis with all its symptoms—lasting three months. The usual treatment was prescribed: atropine sulphate drops 1 and heat applications. Now another attack of iritis is developed in the same eye, and after five weeks there is no appreciable change. What is the accepted modern treatment of iritis?

A.—Little is known of the aetiology of either ulcerative colitis or iritis; an association of the two conditions is not established, but it cannot be excluded that in a particular patient both affections may have the same underlying cause. A full investigation of the patient is highly desirable. The treatment of iritis is still largely symptomatic and does not extend beyond the measures indicated in the question. Refinements in the application of atropine consist in the subconjunctival injection of mydracaine (a specially prepared solution of atropine sulphate 1/60 gr. (1.1 mg.), cocaine hydrochloride 1/10 gr. (6.5 mg.), and adrenaline 1/600 gr. (0.11 mg.) to 5 minims (0.3 ml.). Such injections can be given daily in doses of 5 to 7 minims (0.3–0.4 ml.), and sometimes help in breaking down recently formed adhesions in cases where atropine has failed. Heat may be applied by means of short-wave diathermy given by an expert physiotherapist.

Pyloric Stenosis

Q.—What is the best way to prescribe atropine methyl nitrate in a case of congenital pyloric stenosis? I have seen it recommended as 3 to 5 ml. of a freshly prepared 1 in 10,000 solution or as 0.6% in alcohol (4 drops). Which preparation would keep better, and for how long?

A.—The alcoholic solution keeps better and longer. Few drops of it are required to 1 ml. of the watery solution. Many children's physicians prefer to use the "lingual" form—placing under the tongue and securing, apparently, maximum absorption. Each one contains the equivalent of 1 ml. of the 1 in 10,000 watery solution. If stored in a dry place and at room temperature (and in the manufacturer's "cellophane" wrapper) these keep more or less indefinitely.

Intra-arterial Penicillin

Q.—Has the arterial injection of penicillin been tried? Osmotic pressure tends always to attract water, and if the osmotic pressure of the blood is lowered the fluid is drawn out with resultant exudation, would the injection of a hypertonic solution of saline in which the penicillin is dissolved be better than an isotonic solution? Further, does time affect the controlling factor in tissue-fluid formation, would it be advantageous to advise free movement of the limb involved after the injection? Finally, is the practice of arterial injection too painful to merit its use?

A.—The intra-arterial injection of penicillin has been discussed twice in this Journal quite recently—in an editorial on Dec. 27, 1947 (p. 1040), and in a letter from G. M. D. (Feb. 7, 1948, p. 274). The use of a hypertonic solution would be unlikely to have the effect described unless the volume was large and stasis was produced for a long period; there would also be some risk of haemolysis. It is also doubtful whether active movement would make much difference to the effect. The usual method of ensuring diffusion from the vessel is to raise the pressure in them by occluding venous return for a short period. Intra-arterial injections are decidedly painful, but evidently not too painful in view of the experience quoted.

Blood from the Umbilical Cord

Q.—Will blood taken from the maternal side of the umbilical cord following delivery give a positive reaction to the Wassermann and gonococcal complement-fixation tests in the case of mothers suffering from syphilis and gonorrhoea?

A.—Yes, blood taken from the maternal end of the umbilical cord may give positive reactions to the Wassermann and gonococcal complement-fixation tests, just as would blood taken from an arm or other vein of the mother. It must be remembered, however, that a negative W.R. does not exclude syphilis and that a positive G.C.F.T. is usually obtained only when the gonococcal infection is well established or has been the cause of complications.

Oedema of Foot and Ankle

Q.—A patient who twisted her left foot eight months ago now has persistent pitting oedema of the left foot and ankle. This becomes very marked after standing or walking. The swelling is not tender; ankle movements are full and free, and radiographs show no bone injury or abnormality. There are no varicose veins; albumin is absent from the urine; and there is no other obvious pelvic abnormality. Can you suggest a line of investigation and treatment?

A.—This patient should wear an elastic anklet or stocking to control the swelling and should also have regular massage, contrast baths, and exercises for the calf and the intrinsic muscles of the foot. It is possible that the injury has left behind a flat foot or some slight restriction in full joint movement. In the former case the use of an arch support or a wedged shoe is occasionally necessary, and in the latter manipulation under thiopentone. A progressive lymphoedema sometimes follows a sprained ankle, and elastic support is the proper treatment for this.

Menopausal Blood Donors

Q.—A woman suffering from severe menopausal symptoms—in particular hot flushes, cold shivers, etc.—but with no vaginal bleeding, wishes to enrol as a blood donor. Assuming the severity of the syndrome is due to hormonal imbalance, could the altered oestrogen level of the blood adversely affect the recipient?

A.—No; neither the low oestrogen level nor the compensatory high gonadotrophin level which is characteristic of a climacteric disturbance would have any noticeable effect on the recipient of the blood. Even if the amounts of hormones in circulation were grossly disturbed a single administration would not produce symptoms. The hormones would be quickly utilized, inactivated, or excreted. If it were otherwise then surely care would be necessary to distinguish male and female blood for transfusion purposes, and also to grade female blood according to the time in the menstrual cycle at which it was withdrawn.

Persistent Oxaluria

Q.—An otherwise healthy young man has persistent oxaluria in spite of restriction of oxalate-containing foods. He has crises every few months, with right renal pain and oxalate crystals, red cells, and albumin in the urine. Radiographs are negative. What treatment do you suggest?

A.—It may be difficult to control the attacks in patients with the "oxalic acid diathesis." Some psychiatrists have claimed that such attacks are a symptom of overweening ambition. Only part of the oxalate excreted in the urine is exogenous; this can be diminished by excluding from the diet the oxalate-containing foods: spinach, rhubarb, gooseberries, carrots, oranges, red-currants, and strawberries. The other aim of treatment is to increase the solubility of oxalates in the urine by increasing its acidity, lowering its calcium content, and raising the quantity of magnesium excreted. This is most likely to be effected by a high-protein diet with a relatively small quantity of carbohydrate and by the administration of acid sodium phosphate.

NOTES AND COMMENTS

The Doctors' Dilemma.—Mr. Ritchie Calder, science editor, complains of comments we made on his article entitled "The Doctors' Dilemma" appearing in the *News Chronicle* of Jan. 28. We withdraw any imputation of deliberate misrepresentation of the facts by Mr. Calder or any unintentional reflection on his professional integrity and accuracy as a science writer.

Phosphaturia.—Dr. G. H. DAVY (London, W.) writes: In answer to the question whether there is any relation between phosphaturia and acne rosacea, fibrositis, insomnia, or other nervous disorders ("Any Questions?" Feb. 28, p. 426), no mention is made of the fact that the condition is a very frequent symptom of any anxiety state. In fact it is a not uncommon presenting symptom—patients coming up with the fear that the condition is spermatorrhoea, to which they attribute their debility. I have seen it in peptic ulcer, where it may be due to the general anxiety of the diathesis. In other cases it is due to excessive doses of alkalis. It may be seen in many patients with conscious worry and anxiety.

It is sometimes the cause of sharp pain at the end of micturition which may last for a few moments after the completion of the act. As this complaint is only made by the male it is obviously due to noticing the whiteness of the flow of urine, which rouses fear that there is something wrong with this important part.

Rectal Prolapse.—Dr. T. S. GOODWIN (St. Leonards-on-Sea) writes: In the treatment of an obstinate case of rectal prolapse in an old lady of 88, which was 6 inches long and of frequent appearance during the last six years, I have had complete success from the method mentioned by Dr. Philip Jabkowitz (Dec. 27, 1947, p. 1066) of introducing a ring of silver wire subcutaneously round the anus. Under general anaesthesia the wire was introduced on a large needle and adjusted to admit the passage of one finger comfortably. There has been complete cure since, with no relapse these two months.

Demodex Infestation.—Dr. R. P. LAWSON (Collingham Bridge, nr. Leeds) writes: Under "Any Questions?" (Feb. 21, p. 376) you publish a question about demodex infestation. My two dogs have recently been infested, one heavily and both for several weeks before the cause of their mange was diagnosed.

On the advice of a veterinary surgeon I bathed them every other day until they had had five baths, and followed each bath by lathering them while still wet with "tetmosol," 1 part to 3 parts of water. This was then allowed to dry on them. For some days afterwards they were full of scurf and lost even more hair, and required thorough brushing and combing. They did remarkably well and there has been no sign of recurrence since the treatment, which was in November. I used 18 oz. of the undiluted tetmosol in all on the two dogs, a terrier and a cocker.

Thorium X for Treatment of Baldness.—Dr. BERNARD GREEN (London, W.) writes: I have used thorium X for a variety and large number of dermatoses over the course of many years and have yet to see any ill effects from its application. Pigmentation sometimes follows, but usually disappears in a few months. Whilst agreeing that for ordinary types of masculine baldness it has no effect and for cases of alopecia totalis and universalis the results have been disappointing, for cases of alopecia areata the results have been gratifying. In controlled experiments (Corsi, *Lancet*, 1947, 2, 506), the conclusion arrived at was that if the hair was going to grow the application of thorium X hastens its recovery. I was in charge of the thorium X clinic at St. John's Hospital. There, cases of naevus flammeus were treated with 1,000 E.S.U. at weekly, fortnightly, and monthly intervals for many months. I followed up all these cases for over four years and in no case had I seen any ill effect.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY MARCH 20 1948

HEARD AT HEADQUARTERS

In Lieu of Emoluments

The London County Council, as part of its policy of consolidating salary scales, has been looking into the question of allowances in lieu of emoluments which are made when it is impracticable to provide the emoluments to which a member of the staff is entitled. Certain deputy medical superintendents will henceforth receive a residential allowance of £175 instead of £150, which has been the figure hitherto; others, as well as senior "resident" surgeons, physicians, obstetricians, and aestheticians, will receive £160 instead of £130, and all other medical staff entitled to the residence emolument £150 instead of £120. The working out of allowances in lieu of meals on duty provides some amusing examples of the nicely calculated sums and more. If, for example, you are a medical officer with a salary of over £1,750 a year, your allowance for breakfast will be 1s. 1d., for lunch 1s. 3d., for dinner 1s. 5d., for tea 5d., and for supper 1s. 1d. Your less fortunate colleague who receives a salary of between about £900 and £1,300 will receive exactly the same amounts in lieu of four of the meals, but for supper he will receive only 10d. He is evidently expected to be a little hungrier to bed. The highest salaried post carries a laundry allowance nearly three times as high as the lowest, but all alike receive the same allowance for medical attendance—namely, £4 a year.

Correspondence

Enlarged Thyroid: A Correction

SIR,—I write to correct erroneous impressions which may have been derived from a report (Feb. 28, p. 36) of a lecture I gave to the East Yorkshire Branch of the B.M.A. I stressed the difficulty of deciding when the thyroid gland could be considered enlarged. I quoted from an American work, and also some figures of my own relating to the incidence of thyroid enlargement in diabetes mellitus. In diabetes mellitus 8% of the patients attending a large clinic had palpable enlargement of the thyroid gland. I considered, however, these figures misleading because of (1) the preponderance of women in the clinic, (2) the fact of the presence of another endocrine disease—namely, diabetes mellitus. I did, however, stress the importance of this fundamental fact because the main difficulty in the diagnosis of thyrotoxicosis was not in the severe cases but in the milder cases. Anxiety states were often associated with symptoms almost identical with those of a mild degree of thyrotoxicosis. If patients with anxiety symptoms had a palpable gland it was very easy to say that the diagnosis was one of thyrotoxicosis and overlook the fundamental disability—namely, that of an anxiety state. I stated that surgery still affords the patient the best chance of a complete cure. It was essential, however, that surgery should be performed by a surgeon who was regularly engaged in this special branch. The results from the Means Clinic in America, probably the most efficiently organized clinic for the study of thyroid diseases, showed that the rate of mortality for surgically treated cases was of the order of 2% and that the chances of complete cure were of the order of 70%. Taking

the figures from a teaching hospital where general surgeons of considerable competence merely operate upon the odd case during the year, the mortality rate for thyroidectomy was of the order of 10%, and the percentage of patients cured only of the order of 50%. Therefore I stressed the need, when considering surgery, to refer the patient to a surgeon experienced in the technique of thyroidectomy and preferably to a centre where a surgeon and physician were working in close co-operation.

I doubted the value of thioracil for the long-term treatment of all cases of thyrotoxicosis. There was, however, no doubt as to its value in preparing the serious case, and particularly the cardiac case, for operation. Thioracil had reduced the operative risk in the severe cases to that of a mild to moderate severe case.—I am, etc.,

Department of Medicine,
University of Leeds.

R. E. TUNNICLIFFE.

Medical Staff Representative Committee

SIR,—A Medical Staff Representative Committee has recently been formed at the Sutton Emergency Hospital with the following objects and aims:

(1) The Committee shall consist of members elected by the medical and dental staff so as to provide a balanced representation of the different grades among the medical and dental staff of the hospital.

(2) The Committee shall meet regularly once a month, with intermediate meetings as required. At appropriate intervals it shall report back to a meeting of members. The Committee shall consist of members elected annually. Casual vacancies shall be filled at meetings of the staff.

(3) The general aim of the Committee shall be one of constructive service to the hospital and the promotion of co-operation among the medical and dental staff, and between them and the other groups of staff.

(4) Subject to the exclusion of matters which call for negotiation between the organizations of employees and the employers, there shall be free discussion among the members of the Committee and with the appropriate officers of the hospital of any matter affecting the work and efficiency of the medical and dental staff and the general well-being. All matters appertaining to the treatment and comfort of patients should be separate matters for consideration by the Committee.

(5) The Committee shall, as a result of such discussion, put forward recommendations to the Medical Superintendent and, where desirable, to the appropriate committee.

(6) The Committee shall endeavour to promote co-operation between this hospital and other hospitals in the Region.

(7) This Constitution may be added to, altered, or amended at a meeting of the members of the medical and dental staff after due notice has been given.

We understand that similar medical representative committees are already in existence in some hospitals within the S.W. Metropolitan Region. Others may well be proposed. The Committee would welcome any news of such action, proposed or intended, in the general aim of forming a S.W. Metropolitan Regional Hospitals Association similar to that already established in Liverpool and proposed in the N.E. Metropolitan Region. The Secretary, Dr. A. R. Samuel, at Sutton Emergency Hospital, Brighton Road, Sutton, Surrey, would be glad to hear from those interested.—We are, etc.,

D. SIMON,
General Secretary.
D. E. BIRNBY,
Vice-Secretary.
A. R. SAMUEL,
Secretary.

Sutton, Surrey.

PANEL FOR POOR LAW MEDICAL RELIEF

In view of difficulties experienced in obtaining a district medical officer for the Chiswick medical relief district, the Middlesex County Council has decided, subject to the sanction of the Minister of Health, that arrangements should be made with general practitioners in the district to attend any persons in receipt of poor-law relief. All such practitioners will be circularized by the county council and invited to submit their names for inclusion on a panel of doctors willing to attend any persons referred to them by the Council's relieving officers.

The remuneration will be on the basis of 2s. a surgery consultation and 4s. a visit to the patient's own home, plus a temporary addition of 20% in respect of increased practice expenses. The fees are those which are used annually by the county council when calculating the salaries to be paid to district medical officers for the ensuing financial year. In this payment the cost of any necessary medicines or dressings is not included, the council paying for any such requirement prescribed by the doctor at N.H.I. rates to any dispensing chemist selected by the patient. The Minister of Health, so it was reported at the meeting of the council on Feb. 25, has not yet given his sanction to the suggestion, but has asked to have a draft of the proposed scheme for consideration.

RELEASE OF SERVICE MEDICAL OFFICERS

The Central Medical War Committee has received notification of the following arrangements for release of medical officers in Class A during the second quarter of 1948:

Royal Navy

April 1-June 30: No release.

Royal Army Medical Corps

General Duty Medical Officers.—April: Group 67; May: Group 68; June: Group 69.

Specialists in Medicine, Surgery, and Diseases of Women and Children.—April 1-30: Group 62; May 1-14: Group 63; May 15-31: Group 64; June 1-14: Group 65; June 15-30: Group 66.

All other Specialist Medical Officers.—April 1-14: Group 60; April 15-30: Group 61; May 1-14: Group 62; May 15-31: Group 63; June 1-14: Group 64; June 15-30: Group 65.

Royal Air Force

April: No release; May: Group 69; June: No release.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar.

Non-County Borough Councils.—Dartford, Radcliffe (limited to future appointments), Tottenham, Wallsend.

Urban District Councils.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Portslade, Redditch (restricted to new appointments), Tyldesley.

Scottish Burghs.—Motherwell and Wishaw.

Members of the staffs of many hospitals have in the last few weeks passed by large majorities resolutions against serving under the N.H.S. Act as it stands. The hospitals include the following: Margate General Hospital; Birmingham and Midland Hospitals for Women; Barnet Wellhouse Hospital; Royal Buckinghamshire Hospital; Herefordshire General Hospital; Gordon Hospital, S.W.I.; South London Hospital for Women and Children; Blackburn and East Lancashire Royal Infirmary; Chelsea Hospital for Women; Croydon General Hospital; North Devon Infirmary; Huddersfield Royal Infirmary; Kent and Sussex Hospital; Middlesex Hospital; Royal Free Hospital; South London Hospital; Stirling Royal Infirmary; Sutton and Cheam General Hospital; Warwick Hospital; King Edward VII Hospital, Windsor; Worcester Royal Infirmary; Northampton General Hospital; Carshalton, Beddington, and Wallington District Hospital; Hospital of St. John and St. Elizabeth, N.W.S.; Queen Mary's Hospital for the East End; National Temperance Hospital.

Association Notices**DIVISIONS IN NORTHERN IRELAND BRANCH**

Notice is hereby given by the Council to all concerned:

(1) That a new West Down Division of the Northern Ireland Branch be formed with the following area:

That part of County Down lying to the west of, but including, Magheralin, Dromore, Castlewellsan; that part of County Armagh south of, but including, Newtownhamilton and Bessbrook.

(2) That the Portadown and West Down Division be renamed the County Armagh Division, comprising the area of County Armagh north of, but excluding, Newtownhamilton and Bessbrook.

(3) That the area of the Belfast Division be redefined as follows:

The City of Belfast; that part of County Antrim south of, but excluding, Toomebridge, Ballymena, Carnlough; that part of County Down lying east of, but excluding, Magheralin, Dromore, Castlewellsan.

CHARLES HILL,
Secretary.

Diary of Central Meetings

24 Wed. Council, 10 a.m.

Branch and Division Meetings to be Held

BIRMINGHAM: CENTRAL DIVISION.—At 154, Great Charles Street, Birmingham, Tuesday, March 23, 8.15 p.m. Clinical meeting conducted by Dr. D. Evan Bedford.

NORTH OF ENGLAND BRANCH.—At Royal Victoria Infirmary, Newcastle-upon-Tyne, Thursday, March 25, 7.15 p.m. Clinical demonstration by Mr. W. A. Hewitson: Carcinoma of the Breast; 8.45 p.m. Address by Prof. G. Grey Turner: Some Considerations in the Surgery of the Mouth and Jaws.

Meetings of Branches and Divisions**DUMFRIES AND GALLOWAY DIVISION**

A meeting of the Division was held on March 7, with Dr. A. Kellie Brooke in the chair. The following instructions were given to the representatives appointed to attend the Representative Meeting at Edinburgh on March 10 and the Special Representative Meeting in London on March 17:

(1) That we, as a Division, put in the forefront of the instructions to our representatives that the retention of the ownership of our practices is a vital point. (2) That in no circumstances do we accept a basic salary. (3) That while we dissociate ourselves from the principle of a basic salary we recognize that payment on a capitation basis to rural practitioners would be inadequate. (4) That an increased mileage grant is the most equitable way of balancing up the payments to rural practitioners as against urban practitioners. (5) That we are strongly opposed to any diminution in the capitation fee as a practice increases in size. (6) That we should press for full remuneration in accordance with the recommendations of the Spens Committee Report. (7) That we are opposed to any form of direction by His Majesty's Government. (8) That we should press for the right of appeal to the courts of law. (9) That we should ask for the timely publication of the B.M.A. Council's plan of action which it proposes to put into effect if further negotiations with the Minister of Health break down.

EDINBURGH AND SOUTH-EAST OF SCOTLAND BRANCH

Sir Ernest Rock Carling, speaking on March 5 on "Hazards of the Atomic Bomb, and Casualty Service in Civil Defence," prefaced an instructive summary of the effects of atomic bombing with the assurance that adequate shelters are a good defence against the atomic bomb as at present known. Lantern slides of bomb damage and casualties at Hiroshima gave grim visual emphasis to his description of the effects of blast, flash burn, fire, and radiation, and indicated the vast medical resources required to cope with such casualties. Radiation effects were estimated to have caused 7% of total casualties, and were limited to two miles, although persistent radioactivity would be much more widespread from a bomb detonated on soil or water. Protection from radiation effects was afforded by 18 inches of concrete. The effects might be early or delayed, and were agranulocytosis, haemorrhages, stomal ulceration and gangrene, epilation, anaemia, wasting, and death, or recovery in milder cases. Treatment was very limited, and included intensive blood transfusion with whole blood, penicillin to combat secondary infection, and high vitamin and calorie intake. Genetic effects had not yet been fully estimated, although there was a great increase of miscarriages and premature births in the affected areas.

Civil Defence would have to be based on adequate shelters and warning systems, dispersal, and the organization of aid to come from outside the target areas. Defence services should be staffed by a highly skilled nucleus, aided by a widely organized second line of semi-skilled personnel, assisted at need by the total population as unskilled workers. Throughout history a defence against new weapons was always forthcoming and there was no reason for panic.

DE FORMATIONE OVI ET PULLI

BY

H. A. HARRIS, M.A., M.D., D.Sc.
Anatomy School, Cambridge

FIG. 1.—6½ hours.

FIG. 2.—9 hours.

FIG. 3.—12 hours.

FIG. 4.—23½ hours

FIG. 5.—25½ hours

The year 1621 saw the publication at Padua of a most elaborate treatise on "The Formation of the Egg and of the Chick" by "late the very celebrated anatomist of Padua, Hieronymus Fabricius of Aquapendente," who died in 1619. In 1942 Howard B. Adelmann, Professor of Histology and Embryology in Cornell University, published his scholarly translation with a facsimile edition in the Latin of the two classical works of Fabricius, *De Formatione Ovi et Pulli* and *De Formato Foetu*. This book is a magnificent contribution both to the history and to the philosophy of medicine.

The school of anatomy at Padua produced a race of giants—Alexander Benedictus, Andreas Vesalius, Realdo Columbus, and Fallopius. The death of Fallopius in 1562 was followed by three years of temporary appointments, but in 1565 Fabricius was appointed to the chair of surgery and was enjoined to add instruction in anatomy to his other duties. Between 1565 and 1584 his salary was increased sixfold, from 100 florins to 600. In 1600 Fabricius was appointed Professor Supraordinarius in Anatomy, with an increased stipend of 1,000 scudi, and instruction in surgery was entrusted to Casserius. Fabricius retired in 1613 from active teaching and died in 1619 at the age of 82 or 86, or the year of his birth is given as 1533 or 1537.

Subsequent to Aristotle, Fabricius gave the first analysis of the life history of the egg, based on observation of the

successive stages. He described in greater detail the two twisted cords of albumen, the chalazae, which tether the yolk. He recognized that the egg rotates as it descends through the oviduct, and that the albumen first deposited is thicker than subsequent layers. He was most accurate when describing the formation of the shell. He asked the question: "Why does the egg emerge blunt end first?" He described accurately the "air space" at the blunt end of the egg, noted its slight eccentricity, its increase in size on keeping, and its considerable increase during incubation.

Recently Mr. J. R. G. Bradfield, of the Department of Zoology, has studied the problem of the laying of the egg in the domestic hen. The work was carried out in the School of Anatomy with the active assistance of the

radiographer, Mr. J. A. F. Fozzard, who was awarded the Rodman Medal of the Royal Photographic Society for the excellent photography here displayed. Lateral radiographs were taken at stated intervals and have added to our knowledge, but the significance of all the facts still awaits clarification.

It is known that about 26 hours elapse between the laying of successive eggs. This period of 26 hours is subdivided roughly into:

Half an hour between laying one egg and discharging the next ripe ovum with its yolk from the surface of the single left ovary. Half an hour in passing through the abdominal ostium or funnel of the oviduct. Three hours in the magnum of the oviduct, where the albumen is secreted over the rotating yolk. One hour in the isthmus of the uterus, where the thin shell membrane is secreted. Twenty and a half hours in the uterus, where the calcareous shell is secreted.

The earliest trace of calcium deposition is first visible as a very thin hair-like line on the negative (as distinct from the print) about $6\frac{1}{2}$ hours after laying the last egg (Fig. 1). At 9 hours the density is increased (Fig. 2). At 12 hours the outline of the shell is distinct, with the pointed end of the egg in advance (Fig. 3). At $23\frac{1}{2}$ hours after laying the last egg the pointed end of the new egg is still in advance (Fig. 4). Now occurs one of the strangest movements. During the 24th and 25th hours the egg rotates on its vertical short axis in a horizontal plane so that the pointed end is up-stream and the blunt end presents to the cloaca (Fig. 5). It is not yet known whether this late rotation is constant in direction.

How is this rotation accomplished, and why? The egg is not finally laid in the 26th hour by mass peristalsis. It is not extruded by contraction of the uterus in the manner of a bolus moving along the intestine. The terminal part of the uterus with the contained egg can be seen prolapsing through the cloaca. The uterus is then withdrawn, leaving the egg outside, covered by a viscid fluid which hardens or dries immediately on contact with air. As Fabricius says, "This you will easily observe if you keep a hen at home and dexterously catch her egg in your hand as it is laid." And again, as evidence of the age of the art of palpation, Fabricius says: "In a live hen, too, an egg provided with a hard shell may easily be palpated superficially. Housewives daily make this test when they try the hardness of an egg with their fingers from outside the body in order to find out whether or not the hen is soon going to lay."

It is suggested that the egg rotates and the hemispherical blunt end is presented in advance because it has the surface area which conforms most snugly to the mucous membrane of the dilated terminal portion of the uterus. Wherever all raised water tanks in this country are built with flat bottoms, our American cousins learnt long ago to build them with hemispherical bottoms. The area of the plane circular floor of a cylinder is πr^2 , but the area of the hemispherical bottom is $2\pi r^2$. In short, the latter tank can stand twice the head of water of the former or, alternatively for the same head, the material can be reduced to one-half the thickness of the former. The presenting blunt end of the egg gives the better arrangement for avoiding both rupture of the egg and rupture of the uterus.

In 1873 the Rev. Samuel Haughton, M.D. of Trinity College, Dublin, applied one of the celebrated problems of Lagrange to the act of parturition. It is the problem of the equilibrium of a flexible membrane subjected to the attraction of given forces.

$$P = T \times \left(\frac{1}{r_1} + \frac{1}{r_2} \right)$$

where P is pressure, T is tensile strain in the tangential

plane, and r_1 and r_2 are the radii of curvature. At the presenting membranes the two radii are almost equal, and so $P = \frac{2T}{r}$.

Haughton calculated that the surface of the gravid uterus is 270 sq. in. (1,765 cm.²), the volume 402 cu. in. (6,588 cm.³), the weight of muscle in the uterus 1.56 lb. (0.7 kg.), and the maximum hydrostatic pressure inside the uterus produced by contraction of the muscle 3.4 lb. per sq. in. (239 g. per cm.²). Matthews Duncan and Tait in 1868 had found experimentally that the mean rupturing pressure of the membranes was 1.2 lb. per sq. in. (84 g. per cm.²). In short, the uterine muscle can always rupture the membranes, and in general has three times the strength necessary.

In the case of the hen the uterus is confronted with the passage of a solid egg, and considerations of hydrostatic pressure of the liquor amnii do not satisfy the circumstances. There have been some measurements of the tensile strength of the vitelline membrane surrounding the yolk, and Moran recently calculated it as 4,500 dynes per sq. cm., or 0.06 lb. per sq. in. There are but few estimates of the tensile strength of the two distinct membranes next to the egg shell, or of the shell itself. Romanov in 1926 stated that the average thickness is 0.311 mm. and the breaking strength 4.46 kilos, or 9.8 lb.—somewhat greater than the average man can apply to the egg when held in the palm and fingers.

Haughton said: "Happy is the man whose mother possessed the hereditary tendency to form no more uterine muscle than was absolutely necessary to push him into the world." In similar Lamarckian vein may we say, Happy the chick whose mother hen possesses the necessary uterine muscle to rotate the egg in the uterus, deliver it blunt end first, and yet avoid both rupture of the egg shell and of the maternal uterus.

It is possible that Haughton's earlier years may have been one long Lent, for his father, James Haughton, philanthropist, friend and supporter of Father Mathew and O'Connell during the great potato famine of 100 years ago in Ireland, was also president of the Vegetarian Society.

The domestic hen, who, like the cow, has become a foster-mother of the human race, still presents problems in anatomy, physiology, and biochemistry. So does the cow as regards the mysteries of lactation. It is well to think of this at a time when Easter eggs are in short supply.

The National Association for Mental Health has recently published its report for the year 1946-7. It gives an outline of the Association's many activities, which include lectures to medical practitioners, teachers, social workers, and many special organizations; research into the social adaptation of children brought up in institutions, carried out under the direction of Dr. Bodman; and proposals for the International Congress on Mental Health to be held in August. The Association has charge of four homes for mentally defective children at Rhyl, Bognor Regis, Basingstoke, and St. Leonard's-on-Sea. It runs nine hostels for county agricultural committees. The inmates are selected for their suitability for agriculture, and reports on the value of their work are enthusiastic—such comments as "the most reliable form of labour" often being heard. The hostels altogether accommodate 300 men in Gloucestershire, Hampshire, Shropshire, and Yorkshire. The Association's journal *Mental Health* will now appear four times a year and the subscription has been raised to 5s.

ENVIRONMENTAL FACTORS INFLUENCING HEALTH AND EFFICIENCY IN WARSHIPS*

BY

F. P. ELLIS, O.B.E., M.D.

Surgeon Commander, Royal Navy

When the designers plan the allocation of space and the installation of equipment in warships they have to effect a satisfactory compromise between many requirements, including those for providing in one ship an optimum number of useful weapons and detecting devices, high-powered engines for achieving high speeds, armoured protection against bombs or shells, watertight compartments to enable damaged ships to remain afloat, and, lastly, living and working conditions under which men may remain healthy and work efficiently.

It is one of the tasks of the Royal Naval Medical Service to advise the Staff when this balance of conflicting interests may act unfavourably towards the men and impose adverse effects on their health or efficiency. It will be seen that in the past the acceptance of standards which fell short of those required by the highest dictates of environmental hygiene was unavoidable at times; but the circumstances were such that the alternative would have been unacceptable loss of fighting efficiency in other ways, or a reduction of the safety factor.

In recent years the attention of those responsible for the efficiency of the armies, navies, and air forces of the World Powers has been drawn repeatedly to the fact that the power of modern weapons and the efficiency of fighting machines may be reduced because of neglect to consider sufficiently the characteristics of the men concerned with their operation. This has led to a renewed stiffening of opinion concerning the relative importance of human factors in the design of equipment. These factors may be examined broadly in relation to the physical or psychological ability of the men to carry out their various tasks, or in relation to limitations imposed on them by the nature of their environment. In practice these considerations are usually merged together, and to study one it is necessary to have a good working knowledge of the other.

When war was declared in 1939 the Navy had not for 130 years conducted a major campaign which entailed ships remaining continuously at sea in tropical waters, and the constructional features and design of ventilating arrangements were mainly based on experience gained in operating in temperate or subtropical waters. Although the ill effects of nutritional deficiency and infectious disease, which had ravaged the fleets in the past, were rarely seen, warships were still desperately crowded when they carried their full war complements, and the enormous power generated by their machinery produced great quantities of heat below decks which were hard to control by normal ventilating methods.

The efficiency of ships' ventilation systems was determined until recently by measurement of their ability to keep the level of carbon dioxide in the air of occupied compartments below 7 parts in 10,000. Compartments ventilated to accord with this standard were found, however, to be uncomfortably warm in the Tropics, and in 1937 the decision was made that ventilation arrangements would be designed thenceforward with the aim of maintaining an equable thermal environment under the

climatic conditions generally imposed on warships, a decision easy to make but difficult to carry out.

The early years of the war saw a tightening up of precautions for increasing the watertightness of ships damaged in action by increasing compartmentation and reducing communications between compartments, such as those afforded by ventilation trunking deemed to be unessential. These developments, combined with the "black-out," further complicated the task of those who had to provide satisfactory living and working conditions.

While the main activity lay in home and northern waters the increasing warmth in ships did not hamper operations, but the early Mediterranean campaigns gave warning that when the Fleet operated in the Tropics conditions incompatible with reasonable efficiency might be encountered in certain situations. Thus in 1944, when the Japanese campaign became imminent, the Royal Naval Personnel Research Committee of the Medical Research Council, which had previously devoted its attentions to problems of operational divers, anti-aircraft defence, cold-weather clothing and body protection, was directed to examine the environment of men in warships in the Tropics and to report on the probable effect on fighting efficiency.

This direction was expanded later to include more general problems, conditions in submarines, and problems of the thermal environment in temperate and northern waters. The specialized problems of the naval airman in the air were dealt with by the Flying Personnel Research Committee of the Air Ministry and will not be discussed here. Much of the work subsequently carried out has been reported or is to be reported elsewhere; other studies are not yet complete. It is therefore possible to refer only to the interim conclusions of these investigations.

Surface Ships

It is convenient to consider the various living and working spaces of warships in separate groups according to the activities of the men who occupy them, and the complexity of the problem is indicated by the varying nature of the average thermal conditions. The observations described below were made during a four-month period in 1944 in eleven ships of the Eastern Fleet, including battleships, aircraft carriers, cruisers, and destroyers.

Thermal Environment

The thermal conditions below decks were measured in accordance with the recommendations of B-ford (1946), and were described in terms of the "normal" effective temperature as well as the more conventional dry- and wet-bulb temperatures. The effective temperature may be defined simply, if the air movement and dry- and wet-bulb temperatures of the air are known, from the charts constructed by Houghten and Yaglou (1923) in the United States. This scale of warmth expresses as a single figure the summated effect on the comfort of lightly clothed human beings of air temperature, humidity, and air movement. At the higher ranges of warmth it does not afford an accurate index of the physiological effects of the possible combinations of these three factors, and the practicability of replacing this scale with a concept based more closely on the physiological and psychological responses of individuals is being examined. During the war effective temperature was the most suitable common index available, and over the range of conditions generally encountered it was satisfactory for our purpose.

Houghten and Yaglou also constructed a "basic" effective temperature chart which referred to the comfort sensations of men stripped to the waist. Warship crews in action, however, generally wear overalls and anti-flash hoods and gloves to protect them against flash burns. The normal effective temperature chart was therefore used in describing the measurements made on this survey.

*The basis of a paper given to the Society of Medical Officers of Health (Services Hygiene Group) on Nov. 28, 1947.

Allowance was made for the effects of radiant heat where these were important by making globe-thermometer measurements also and computing the mean radiant temperature of the surroundings; or, alternatively, by applying a correction to the effective temperature scale by substituting the globe-thermometer readings for those of the dry-bulb thermometer when reading the chart.

Bedford (1948) has pointed out that recent American studies on the effects of radiant heat on rectal temperature showed that "corrected effective temperature" fitted the experimental findings when the average rectal temperature of the subjects of the experiments was 100° F. (37.8° C.), over-corrected for radiation under more severe thermal conditions and under-corrected for it when the environment was less severe. The concept of corrected effective temperature may be used, therefore, only to give an approximation of the added strain imposed if heat radiation is added to the other thermal factors of a man's environment.

The standards provisionally accepted by the Admiralty since 1944 in planning warship ventilation for the Tropics state that 80° F. (26.7° C.) effective temperature (or corrected effective temperature if radiant heat is a factor) is the upper desirable limit for thermal conditions in spaces where men must live and work, and that 86° F. (30° C.) effective temperature (or corrected effective temperature) is the upper acceptable limit.

It is necessary to interpret these standards with considerable latitude in considering different compartments. The severity of

of efficiency, and remained healthy. The men on deck were reliant on carefully designed clothing for protection against cold, wet, and wind. The thermal environment here was apparently less critical than in the Tropics, but the effects of conditions in the Arctic regions have not been the subject of detailed investigation in recent years.

Accommodation

Sir Sheldon Dudley, in his preface to *Environmental Warmth and its Measurement* (Bedford, 1946), stated: "The problem to be solved by research and experiment can be stated briefly, thus—What is the ratio of the space allocated to the human element, to the space allotted to the mechanical element of the total fighting machine (ship plus ship's company) which will make the most efficient engine of war?"

A review of the space available for a community of nearly 8,000 men who were living on the mess decks of two battleships, four cruisers, an aircraft carrier, and an escort carrier in the Eastern Fleet showed that less than 150 cu. ft. (4.25 m.³) of space per man was provided on the mess decks for 69% of these men and their belongings and less than 200 cu. ft. (5.66 m.³) for 92%. The height of the deckhead is usually about 8 ft. (2.4 m.) in warships. Thus the majority of ratings were entitled to a floor area of less than 19 sq. ft. (1.76 m.²). It is interesting to note that Dudley (1928) reported similar arrangements for the crew in H.M.S. *Dunedin*. Satisfactory air hygiene was obtainable under these congested conditions by high ventila-

TABLE I.—Average Thermal Conditions in Living and Working Compartments in Surface Ships of the Eastern Fleet (1944)

	Normal Effective Temperature	Dry-bulb Temperature	Wet-bulb Temperature	Air Movement per Minute	Relative Humidity	No. of Observations
Mess decks	84.0° F. (28.9° C.)	90.0° F. (32.2° C.)	82.0° F. (27.7° C.)	100 ft. (30.48 m.)	71%	947
Machinery spaces	88.7° F. (31.5° C.)	102.7° F. (39.27° C.)	87.7° F. (30.94° C.)	468 ft. (142.65 m.)	55%	359
Gunnery control compartments	86.5° F. (30.28° C.)	95.5° F. (35.28° C.)	84.2° F. (29° C.)	172 ft. (52.42 m.)	61%	364
Gun-turret lower quarters	86.6° F. (30.33° C.)	91.9° F. (33.28° C.)	84.9° F. (29.39° C.)	60 ft. (18.29 m.)	75%	123
Radar offices	86.9° F. (30.5° C.)	97.7° F. (36.5° C.)	83.8° F. (28.77° C.)	160 ft. (48.77 m.)	56%	59
Electrical spaces	89.5° F. (31.95° C.)	104.7° F. (40.4° C.)	82.6° F. (28.11° C.)	147 ft. (44.8 m.)	39%	81
Workshops	87.5° F. (30.83° C.)	100.3° F. (37.33° C.)	83.7° F. (28.66° C.)	193 ft. (58.83 m.)	51%	55
Sick bays	83.0° F. (28.33° C.)	90.9° F. (32.72° C.)	82.1° F. (27.77° C.)	239 ft. (72.85 m.)	68%	82
Communication offices	85.8° F. (29.88° C.)	95.9° F. (35.5° C.)	83.9° F. (28.83° C.)	163 ft. (49.68 m.)	61%	168
Galleys	87.4° F. (30.77° C.)	97.5° F. (36.39° C.)	84.2° F. (29° C.)	192 ft. (58.5 m.)	58%	165

thermal conditions should be assessed in relation to the energy expended by the men exposed, to the complexity of their mental tasks, and to the clothing they must wear. Thus men handling ammunition for the heavy guns would become inefficient in a less severe environment than would engine-room watch-keepers, whose physical tasks might be light in comparison; or a radar operator watching for the faint signals on the display might fail to observe the presence of a ship or aircraft in the vicinity, although an engine-room watch-keeper observing the more plainly displayed dials and indicators in the engine-room under similar thermal conditions would be less liable to make an error; or, again, submarine crews stripped to the waist when submerged in the Tropics could sustain without loss of efficiency severer thermal conditions than the more heavily clothed crews of surface ships in action.

The average dry-bulb temperature on deck was 83° F. (28.3° C.) and the average wet-bulb temperature 77° F. (20° C.) when these measurements were made. The sea temperature varied between 82 and 88° F. (27.8 and 31.1° C.). In the living compartments (mess-decks) the average wet-bulb temperature was 82° F. and the average effective temperature 84° F. (28.9° C.). In the main working spaces of these ships, and in some of the compartments which were especially important in action, the average effective temperature varied from 85 to 90° F. (29.3 to 32.2° C.). In certain spaces, such as machinery compartments, galleys, and workshops, it was found that for nearly 800 measurements made the mean radiant temperature of the surroundings lay between 90 and 120° F. (32.2 and 48.9° C.) for 66%, and between 120 and 150° F. (48.9 and 65.6° C.) for 24%; and "corrected" effective temperatures between 95 and 100° F. (35 and 37.8° C.) were encountered at times.

The thermal conditions in ships in temperate waters gave less cause for concern. In northern waters men below decks were generally able to carry on with their work without loss

of efficiency, and remained healthy. The men on deck were reliant on carefully designed clothing for protection against cold, wet, and wind. The thermal environment here was apparently less critical than in the Tropics, but the effects of conditions in the Arctic regions have not been the subject of detailed investigation in recent years.

The above figures may be compared with wartime standards in naval barracks ashore, which allowed a minimum of 45 sq. ft. (4.18 m.²) of floor space per man and an "austerity" standard of 30 sq. ft. (2.79 m.²) if double-tiered bunks were used for sleeping (Dudley, 1943). The men slept in hammocks in temperate waters, but in the Tropics many found these too hot, and light camp-beds were issued as well, so that up to 70% of ships' companies slept in the open air on the upper deck.

Chemical Factors

The powerful ventilation systems of modern warships prevent undesirable accumulation of products of respiration such as carbon dioxide. Chemical factors are not therefore generally of importance. Reference has been made elsewhere (Ellis, 1944, 1947b) to circumstances which may result in casualties when, as a result of explosions or faults in machinery, contamination of the air of compartments, by nitrous fumes, carbon monoxide, and certain volatile chemicals used as refrigerants and in fire extinguishers, may occur without the knowledge of the occupants.

There is one exception to the above generalization. The magazines and ammunition-handling spaces of ships in action are hermetically sealed to prevent the flash of explosions blowing up their dangerous contents. In war these compartments may be heavily manned for many hours, or even days, and after a period (10 to 15 hours) without ventilation it becomes necessary to guard against undesirably high accumulations of carbon dioxide. The rate of accumulation varies with the size of the compartments, the number of occupants, and the energy expended by them. At an earlier time complaints may be made of headaches and general malaise due to inhaling the volatile

decomposition products of cordite. These effects have been studied by Thomson and Weiner (1947), who have shown that men handling cordite charges are more severely affected in hot humid atmospheres. The gun-crews were clothed in overalls, fabric hoods, and long gloves to protect them against flash-burns. Ammunition compartments were also critically warm and humid in the Tropics (Table I). It may be concluded that ammunition handlers carried out their arduous tasks in the face of considerable difficulties.

Bacterial Factors

The increasing use of air-conditioning equipment in warships led to proposals for economizing in the weight and size of ventilation trunking by effecting considerable reductions in the volumes of fresh air to be supplied to air-conditioned compartments; for the former lavish supplies were based on the need for limiting the thermal conditions, which would now be controlled by refrigeration. It was asked, therefore, if decreasing fresh air supplies and increasing air recirculation would cause undesirable additions to the bacterial content of the air of compartments.

Several serious epidemics of upper respiratory tract diseases which had occurred in ships at critical stages of the war, and the annual rate for pulmonary tuberculosis in the Navy, which had been double that in the other Services for many years (Dudley, 1941), were additional reasons for examining these proposals to reduce fresh air supplies with some precision.

A preliminary survey of conditions in a newly built cruiser and a submarine (M.R.C. Special Report Ser., No. 262) provided interesting data which permitted a comparison to be made between the bacterial environment of naval ratings and that of the civil community. About 600 "two-minute" samples of air were taken with a slit sampler (Bourdillon, Lidwell, and Thomas, 1941) in the cruiser during several days at sea under action conditions and while lying in Scapa Flow.

Previous studies by the Medical Research Council had suggested that under ordinary domestic or working conditions bacterial counts made in this way should not exceed 50 bacteria-carrying particles per cubic foot (0.028 m.³) of air, although much lower levels were desirable in hospital wards, dressing-stations, or operating theatres. It was found that when men were engaged in quiet occupations on the mess decks the above level was not usually exceeded, but it was when there was much activity, such as sweeping up after meals, turning out of hammocks in the early morning, and crowding into the bathrooms before breakfast. These findings indicated a need for making improvements, but did not compare unfavourably with similarly crowded situations ashore. In the critical action-compartments, such as the crowded gunnery-control positions beneath the armoured deck, surprisingly high standards of air hygiene were achieved by the ventilation provided.

In the air-conditioned compartments investigated recirculation of the air did not lead to a build-up of bacteria during two-hour periods. This aspect requires further investigation, and it is also desirable to repeat in the Tropics the general study in ships.

Submarines

Although the first submarine is said to have been navigated in the Thames in the time of James II, they were not developed as naval weapons until the twentieth century, when in two wars they nearly proved to be decisive weapons in the hands of our enemies. British submarines were also a most effective naval weapon, and, in view of the small numbers of men employed, an economical one too. In the Mediterranean alone a total force which rarely exceeded 1,000 men—or the ship's company of a single cruiser—sank between one and two million tons of Axis shipping and paved the way for the success of the Eighth Army by disrupting enemy supply lines. The Germans were late in appreciating that the effectiveness of a submarine on long patrols depended on the provision of an optimum environment for the crew. These environmental problems differ in certain important respects from those of surface ships.

Thermal Environment

When a submarine is submerged and propelled by the electric motors the conditions are ideal for securing a high degree of control of the thermal environment by insulating the pressure hull to prevent large heat transfers between the sea water and the internal surface of the pressure hull, and by using refrigerating machinery for cooling and dehumidifying the air in the Tropics and heating elements and radiators for warming it in the Arctic.

A series of observations made just after the end of the war in a submarine carrying out an Arctic and tropical cruise showed that, even when pressure-hull insulation was only partially fitted, satisfactory control of the thermal environment could be achieved during a diving patrol in tropical conditions off the Orinoco, where the upper desirable thermal level of 80° F. (26.7° C.) effective temperature was rarely exceeded.

When a submarine is on the surface the main engines draw large amounts of air down the conning-tower hatch and aft to the engine-room. In northern waters the crew are probably colder than they would be in surface ships in the same area, while in the Tropics the introduction of so much fresh air reduces the effectiveness of the air-conditioning plant. In rough seas and foul weather the added inconveniences of motion sickness and exposure to cold and wet which handicap many of the crew on surface patrols are practically eliminated when the submarine is submerged.

Accommodation

The cubic space allocated for sleeping and living quarters in large submarines varies from just above to just below 100 cu. ft. (2.83 m.³) per man. Thus the average space available for a man and his belongings is rather less than in surface ships; but the separate messes are divided from each other only by curtains or light partitions, and when the ventilation fans are circulating the air it is more reasonable to consider the entire submarine as a single compartment. It is then found that the volume of breathable air available for each man when the submarine is submerged will be somewhere between 300 and 500 cu. ft. (8.49 and 14.16 m.³) in different classes of submarine, and, provided the sleeping bunks are separated by adequate intervals, this will be more important for providing satisfactory air hygiene than the amount of space actually allocated to each man in each mess.

The best use is made of the space available by ingenious designs of fittings and furniture, and the degree of comfort obtainable is surprisingly high under the circumstances.

Chemical Factors

When a submarine is submerged carbon dioxide will accumulate in the air, which will at the same time be depleted of oxygen by the respiratory requirements of the crew. The rate at which these changes occur will vary with the volume of air available in the different types of submarine, the numbers of the crew, and the energy expenditure of the latter in the duties they must perform.

The careful control of both these factors is essential. The features of oxygen lack are said to include deterioration in visual acuity when the percentage at one atmosphere falls below 19% and, at lower concentrations, impairment of judgment and reasoning faculties, possibly associated with confident unawareness of the dangers involved and a feeling of well-being. Narcotic effects may also result from breathing atmospheres with a high content of carbon dioxide (5 to 10%), and varying degrees of headache and malaise occur in some people after breathing lower concentrations for a few hours. In addition, after regaining fresh air, unpleasant "after-effects" of this type may be experienced.

The time factor is of considerable importance. Past standards for achieving satisfactory air purification have been based on the assumption that periods submerged would not usually extend beyond one to two days at the outside and were usually less than 24 hours. In the event of more prolonged exposure these physiological effects will require re-examination. In the control of these factors reliance is laid on devices for absorbing carbon dioxide and generating oxygen, and on indicators

which keep the commanding officer informed of the chemical composition of the air.

Atmospheric hazards, which occasionally may cause casualties in submarines, include poisoning by carbon monoxide evolved from torpedoes which "run hot" in the torpedo-tubes, battery gases such as chlorine, and volatile chemicals used as refrigerants or in fire extinguishers. The breathing apparatus provided to enable men to escape from sunken submarines is an excellent ready-to-hand self-contained breathing apparatus for rescue or repair work in compartments containing these gases. The refrigerant "freon" (dichlorodifluoromethane) which is generally used in submarines is innocuous if inhaled. Such accidents are uncommon nowadays.

Pressure Changes

During long periods submerged, leaking high-pressure air, and ballast adjustments concerned with maintaining the ship on a level keel, may lead to considerable increases in atmospheric pressure. The physiological effects are not important provided that the partial pressures of oxygen and carbon dioxide are known and suitable precautions are taken before opening the conning-tower hatch.

marine air through the engine-room when submerged, where the bacteria-carrying particles adhered to the oily bulkheads and machinery.

The Effect on Health

The health of men serving in home and northern waters did not give rise to undue concern during the earlier years of the war, but when the majority of ships were transferred to the Indian Ocean and the Pacific in 1944, before the Japanese campaign, it was considered desirable to obtain an overall picture of the reaction of the men to their new environment. Reports were requested from the medical officers of the ships in the Eastern Fleet and later in the British Pacific Fleet. Their examination showed remarkable similarity in the state of health of the men in the two Fleets.

In the Eastern Fleet it was found that on the average each month, for every 100 men in ships afloat, 29 attended the sick bay as out-patients and 5 were made unfit for duty because of ill-health. In the British Pacific Fleet the

TABLE II.—Common Causes of Ill-health in the Tropics: Case Incidence per 100 Man-months

*Excluding prickly heat.

In 1944 and 1945 the Germans fitted to their submarines a device developed by the Netherlands Navy which they called a "Schnorkel." This consisted of a hollow mast which could be raised above the surface to provide air supplies for the interior while the main hull of the submarine remained submerged. The schnorkel supply duct was a relatively narrow tube, and the demands of the engines for air were heavy, so the pressure within these submarines was generally depressed to varying degrees below one atmosphere, and in a choppy sea the intermittent occlusion of the air inlet by a valve fitted to prevent flooding would cause fluctuations of the internal pressure. By the use of this device U-boat commanders remained continually submerged for many weeks while avoiding detection, and it would appear that, provided the machinery was suitably designed and the device was wisely used, ill-effects on the personnel did not result.

Bacterial Factors

During the survey of air-borne bacteria described above 80 two-minute samples of air were collected in a submarine during a day at sea off the Orkneys. It had been suggested previously that the difficulties of ventilating submerged submarines might lead to undesirably high bacterial contamination of the air, although it had often been observed that on long patrols submarine crews were unaffected by serious epidemics of upper respiratory tract infections.

It was found that, under a wide variety of probable operating conditions, the upper desirable level of 50 bacteria-carrying particles per cubic foot of air was exceeded only when there was considerable human activity near to the slit sampler. This excellent state of affairs was attributed to the good ventilation obtainable on the surface and to the recirculation of the sub-

corresponding figures were 28.6 and 4.6. The more common conditions which caused the men to report at the sick bay are shown in Table II.

The amount of ill-health in ships was very much greater than in naval barracks and establishments ashore, mainly because of the predominance in ships of skin diseases (including boils, fungus infections, septic prickly heat, and tropical pemphigus) and other infections of the epidermis such as otitis externa, and also because of the relatively greater incidence of minor injuries. Uncomplicated prickly heat was almost universal in many ships, and the monthly incidence of heat exhaustion in ships of the Eastern Fleet (0.42) represented a rate of 1 man in every 20 per year.

On the credit side the incidence of infectious diseases and malaria remained at a low level. Respiratory tract infections were the most prevalent infective condition in both Fleets. Dysentery, however, accounted for increased ill-health in the Eastern Fleet. Dyspepsia was not a common complaint, and neuro-psychiatric disorders were relatively infrequent. Cruises out of the Tropics to South Africa or Australia were always associated with a great decrease in minor sickness, and the significant role of hot humid atmospheres in the causation of ill-health in the Tropics was undoubted.

Comparable wartime figures are not available for the Home Fleet. Reports from ships made during the first twelve-month period after the Japanese War ended, which gave the numbers of men on the sick-list or attending a

out-patients at midnight each Wednesday, have been analysed by Dr. J. A. Fraser Roberts. These show that the 'average sickness for the period under review was approximately twice as great for ships serving in the Tropics as for those in the Home Fleet, and the figure for ships in the Mediterranean lay between these two extremes. Few ships were serving in northern waters at this time. The increase in the Tropics was found again to be due to skin diseases and minor injuries, and again the ships' companies of depot ships and repair ships were the least healthy in the Fleets.

The Effect on Efficiency

The adverse influence on efficiency imposed by this widespread increase of skin disease and heat illness in the Tropics was unquestionable. It was found that air-crew in a fleet aircraft carrier lost more than three times the number of flying days in three months in the Tropics than did a larger number of air-crew in the same ship in a previous quarter when operating off the coast of Norway. In addition to ill-health the warm environment in itself reduced the efficiency of the men. Work took longer to do, and was not so well done as in cooler climates. Heavy operations, such as "bombing-up" a wing of 24 aircraft, took half as long again as in home waters.

Observations on men working in gun turrets (Ellis, 1947a) showed that the ammunition parties were working under conditions which brought them near to the limits of physical endurance. Submarine crews were prevented by heat and humidity from carrying out full-length tropical patrols until air-conditioning plant was fitted.

The view that the prevailing warmth in ships was detrimental to efficiency was given further support by work at the climatic laboratories of the Medical Research Council by Professor F. C. Bartlett and Dr. N. H. Mackworth at Cambridge and by Dr. E. A. Carmichael and Dr. B. McArdle and their colleagues in London. This work confirmed the main conclusions of Eichna *et al.* (1945) and of Robinson *et al.* (1945) in the United States of America that men could carry on with heavy physical tasks for short periods without collapsing when the prevailing level of warmth was greater than that generally encountered in the Eastern Fleet except in gun turrets in action and certain machinery compartments. The efficiency of wireless operators, however, was found to fall off between effective temperatures of 83 and 87.5° F. (28.3 and 30.8° C.) which were commonly experienced in the Eastern Fleet; and the examination of the effects of warmth on other activities of importance in warships confirmed the conclusion that accuracy, judgment, and concentration over short periods (four hours) were reduced in quality before ability to continue to perform simple but strenuous physical tasks.

Many of the principles of man's reaction to excessive warmth have been examined in the United Kingdom, although the effects of heat radiation require further elucidation. It is now desirable to discover whether men acclimatized by living in ships stationed in tropical waters will show similar reactions to the conditions of the above experiments.

This survey of conditions in ships, similar observations by Royal Air Force observers in aircraft in the Eastern Theatre, precise observations on the effects of desert heat on soldiers by Ladell, Waterlow, and Hudson (1944), research in climatic chambers, and parallel studies in the United States have provided much information on the environmental factors which limit the efficiency of military forces in hot climates. In general this supports the standards which are now used in designing ships' ventilation systems for tropical service.

It is generally agreed that to afford men periodic respite from the heat by the selective application of air-conditioning to certain offices, work-places, and recreational and living spaces offers the best chance of improving the thermal environment of men in warships in the Tropics, but much can be done with soundly designed and operated ventilation systems, and by keeping the air moving with ceiling or bracket fans. More generous application of air conditioning is desirable for those smaller ships which must patrol in the desert-locked waters of the Red Sea and the Persian Gulf, where the severity of the climate far exceeds that normally encountered in the Indian Ocean.

Less is known about the effects of extreme cold on efficiency. There is no sound index for indicating simply the effect of varying low temperatures, humidities, and air velocities on physiological and psychological functions, and information about the optimum levels of warmth to be maintained in ships by artificial heating is incomplete. There is thus a need for further examination of the human factors related to operations under extremely cold conditions, to make available the fundamental facts without which the design of equipment for the Arctic and Antarctic will continue to depend on empirical methods.

Conclusion

Considerable research is being devoted to ways of securing optimum arrangements of working equipment, machinery, and seating, to the designing of instrument controls and displays to enable simple and efficient operation, to anthropometry, and to time-studies for reducing delay or saving man-hours in processes involving several operators or teams of workers. Other investigations are concerned with the definition of optimum lighting intensities and the most favourable siting of sources of illumination for various types of work. The influence of background noise or unexpected sounds on the performance of auditory or non-auditory tasks, and more abstract considerations such as the effects of monotony or repetitiveness on overall efficiency, are being reviewed.

It is not possible here to consider many other factors which affect working efficiency. Little reference has been made to clothing or the psychological aspects of life in warships, the present knowledge of which was reviewed by Critchley (1945), or to less common environmental problems such as those associated with escape from air raid submarines.

From this brief survey it will be seen that the structural features of warships are closely bound up with the requirements of the men. The acute space limitations, the need for securing watertight subdivisions of ships, the heat generated by machinery, and the limitations in the types of ventilating procedures designed for temperate climates make it necessary to secure a sound compromise between meeting these requirements and building efficient pattern ships. We have reached a stage when satisfactory design can proceed only if precise and accurate data are available on the human requirements and limitations and if these can be translated simply into terms appreciated by engineers and designers.

The rapid strides in aircraft construction, shipbuilding, underground engineering, and under-sea activities, and the economic need for providing optimal conditions for workmen in many spheres, have shown that many of the environmental problems which beset the fighting services in war differ little from those of the civil community at peace.

It would seem appropriate that men with a medical education should play a large part in these studies, and in particular that the medical services of the Army, Navy,

and Air Force should play a leading part in integrating the results of research work in the medical and physiological fields in the plans of those responsible for equipment design or concerned with maintaining operational efficiency.

I am indebted to the Royal Naval Personnel Research Committee for permission to publish this account of some of the committee's activities.

PERMANENT HOMONYMOUS QUADRANTANOPIA AFTER MIGRAINE

BY

W. M. RICH, D.O.M.S.

Migraine with visual hallucinations is reported often enough in the literature to need no further amplification. That it can have a permanent effect on vision is not. A case is here described of permanent homonymous quadrantanopia following 20 years of migrainous headaches.

Case History

The patient, a married woman aged 32, has had headaches since she first began to menstruate at about the age of 12. There is some relationship to her periods, but it is not absolute. The headaches have been getting worse during the past two or three years. They always develop in the same way: first there are "flashing lights," and as these fade a "haze" appears on the right side and spreads from above downwards and to the left. With the haze, or soon after, the headache ensues, beginning in front and radiating to the back of the head, becoming most intense occipitally. The patient recently noticed that the "haze" was permanently present wherever she looked and whether she had a headache or not. When I first saw her she had had this shadow in each eye, above and to the right, for about two years. She has been married 14 years and has two children (girls, aged 13 and 7); there have been no miscarriages. She was very thin up to the birth of the younger child, but during the next two years her weight rose from 7 st. 6 lb. (47 kg.) to over 10 st. (63.5 kg.), where it has remained for the past four or five years. Her periods are normal and regular. There is no polyuria or polydipsia.

On examination she was seen to be a well-nourished, placid, intelligent, and apparently healthy young woman. Eye examination revealed: R.V. 6/5, J. 1; L.V. 6/5, J. 1; emmetropic; orthophoric; pupils active to light, both direct and consensual, and to accommodation-convergence, equal and well sustained;

Wernicke's hemianopic reaction could not be obtained; tension (digitally) normal; media and fundus of each eye normal and healthy. The blood pressure was 128/68. Night and morning specimens of urine were normal. The Wassermann reaction and gonococcus-fixation test were negative. X-ray examination of the skull showed that the pituitary fossa was exceedingly small, with ossification of the petro-clinoid ligaments. The only other abnormalities discovered were:

Peripheral Field.—1/330 mm. white was full and normal in each eye, except for a small absolute scotoma, homonymous and quadrantanopic in shape and less than 30 degrees, which was more satisfactorily plotted with the Bjerrum screen. Those for red, green, and blue were similar. Only the white is illustrated (Figs. 1 and 2).

Bjerrum Screen.—5/2000 mm. white, red, blue, and green were taken, but only that for white is illustrated (Figs. 3 and 4). The points to be noted are: sparing of the macula; the clean-cut edge along the 90 degrees vertical and 180 degrees horizontal meridians, and between these the absolute scotoma from 1 to 18 degrees; the relative scotoma for a further 5 degrees where the colour faded; its quadrantanopic shape, homonymous in character, and almost complete congruity. The colours followed an almost identical pattern.

Discussion

Migraine is usually considered to result from vascular instability, the headache being due to spasm of the arteries supplying the occipital cortex, or of the scalp and dura mater, or to irritation of the meningeal arteries following an initial dilatation which produces the sense of well-being. In the present case, however, there is just the possibility of friction on the left optic tract due to calcification of the clinoid ligament; but this seems somewhat unlikely, for the patient was re-examined at three-monthly intervals during the ensuing six months and no change was found.

Traquair (1933, 1942) states that the characteristic feature of optic tract lesions is incongruity, that the fixation area is more often affected when the lesion is in the anterior part of the supra-chiasmal path, that homonymous quadrantanopia is found in damage to the calcarine fissure or to the radiation, that sparing of the fixation area of usually less than 5 degrees is almost constant in occipital hemianopias, and that isolated hemianopia is so rarely due to optic radiation and so frequently to occipital lesions that the latter position should be assumed as the site of the lesion unless there is other and stronger evidence, such as a wound, to implicate the former. While Peter (1938) states that perimetry definitely locates ophthalmic migraine in the visual cortex and that migraine is probably due to spasm of the small vessels in the cuneus and where the scotomata—quadrantic or hemianopic, always bilateral and homonymous—have become permanent, the repeated attacks of spasm in these vessels during the migrainous attacks have resulted in permanent occlusion of the vessel, with softening of the brain tissue, the functional now becoming organic.

It may therefore be safely assumed that in my case this is what has happened rather than the problematical suggestion of friction from an ossified clinoid ligament damaging the optic tract.

Review of the Literature

That there is a connexion between idiopathic migraine, epilepsy, and subarachnoid haemorrhage has been mentioned before. It is not the purpose here to discuss this, but to draw attention to the much greater frequency of hemianopias associated with migrainous headaches either of established or, most probably, vascular origin, irrespective of the age of the patient, and those associated, as in the case described, with idiopathic migraine in which the possibility of vascular origin other than vasomotor instability is most unlikely. Ormond (1913), quoting from his own and other observers' cases, mentioned nine in all, six of which,

MARCH 27, 1948

PERMANENT QUADRANTANOPIA AFTER MIGRAINE

with one doubtful exception, were probably cases of intracranial haemorrhage. In two of the three cases of migraine uncomplicated by a probable vascular lesion there was homonymous hemianopia with sparing of the macula by less than 5 degrees.

At a meeting of the Ophthalmological Society Prof. Unthoff (1914) said that he had seen five cases of persistent

homonymous quadrantanopia, and necropsy showed complete atrophy, strictly limited to the lower half of the cuneus, of the right occipital lobe. The second was recorded by Schiff-Wertheimer (1926). This patient, a man aged 60, had a right superior homonymous quadrantanopia, and necropsy revealed a lesion of the left cuneus, limited to the inferior lip of the calcarine fissure. These two cases,

FIG. 1.—Perimeter field, left eye.

FIG. 2.—Perimeter field, right eye.

FIG. 4.—A: Absolute scotoma. R: Relative scotoma with blurring and loss of colour. (Right eye.)

partial hemianopia following recurrent migraine, and was of the opinion that they were localized to the occipital cortex: Hawthorne (1914) described four cases free from vascular or renal cause in young women, and five others in older patients with a greater or lesser degree of cardiovascular degeneration; and Cross (1914) mentioned 18 of his cases of the latter type, and stated that the common cause was embolism of some twig of the calcarine artery. Johnson (1936) quoted two cases of quadrantanopia which came to necropsy. The first was that recorded by Hun (1887). This patient, a man aged 57, had a left inferior

particularly the latter, support the hypothesis that in my case the lesion will be found in the occipital cortex rather than in the optic tract. The statement by Veil (1930) that transitory hemianopia associated with ophthalmic migraine is of no importance seems to require revision, as does Tidy's (1945) that in rare cases migraine may subsequently result in complete blindness; for Thomas (1907) remarked that "a number of cases are reported [of hemianopia as an aura of migraine] where symptoms appearing during the attack similar to transitory ones in previous attacks have become permanent."

quoted eight cases; four of which were his own. One of these four proved at necropsy to have had an aneurysm of the right posterior communicating artery which had burst; two others were probably vascular in origin, since in one case there was amnesia and in the other paraesthesia; and the last of the four—a healthy young woman of 27—was a case of right permanent hemianopia as a result of idiopathic migraine, with sparing of the macula by less than 10 degrees and otherwise a clean-cut vertical edge above and below. She was re-examined six weeks later, but there was no alteration. The ages of these four patients varied from 15 to 67 and all had had proved intracranial vascular catastrophes.

Peter (1938), quoting Charcot and others in their description of cases of persistent quadrant and hemianopic scotomata following migraine, remarks that other cases have appeared in the literature from time to time; while Adie (1930), drawing attention to permanent hemianopia in migraine, migrainous epilepsy, and spontaneous subarachnoid haemorrhage and their probable interrelationship, describes seven cases in which there was probably a subarachnoid haemorrhage. Dixon (1947), in drawing attention to the frequency of strokes in young adults, mentions four cases of field defect in young people associated with a probable intracranial haemorrhage.

Comment.—In this brief review of the literature 63 cases are mentioned, of which 14 seem to be of true idiopathic migrainous origin, and 49 have been associated with intracranial haemorrhage—a ratio of 2:7. It seems likely, therefore, that many more cases of migraine than appear in the literature would show permanent field defects, that sooner or later a number of these would show other signs of intracranial haemorrhage, embolism, or thrombosis, and that the relationship between migraine, epilepsy, and subarachnoid haemorrhage is closer than has been recognized. Attention is also drawn to its greater frequency in women.

Summary

A case of permanent quadrantopia subsequent to 20 years of repeated attacks of idiopathic migraine is described.

The probable site of the lesion—at first functional, later organic—is discussed.

A review of the literature revealed only 13 other cases.

The National Corporation for the Care of Old People has appointed a committee to make recommendations on grants for old people's homes and their welfare services in Scotland. Sir Hector Hetherington, Principal and Vice-Chancellor of Glasgow University, is chairman of the committee, and the other members are: Dr. A. Craig Anderson, Dr. A. D. Briggs, Dr. R. W. Craig, Miss Grace Drysdale, Prof. Ferguson, and Mr. H. L. F. Fraser. Offices are to be opened at 2, St. Andrew's Square, Edinburgh.

PHLEBOTHROMBOSIS DECUBITI AND PREVENTION OF PULMONARY EMBOLISM

BY

HAMILTON BAILEY, F.R.C.S., F.A.C.S., F.I.C.S.
F.R.S.Ed.

Surgeon, and in charge of the Genito-Urinary Department,
Royal Northern Hospital, London

The assumption that pulmonary embolus is an unavoidable accident is no longer tenable.—J. FINE.

In this article no attempt will be made to describe and discuss the prevention of phlebothrombosis by early ambulation, exercises and massage, or the administration of anticoagulants. Moreover, much as I should like to express my views on the relationship of posture to venous thrombosis, I am anxious to avoid becoming involved in controversies concerning the merits and demerits of Fowler's position. This does not imply that I fail to appreciate that the prevention of phlebothrombosis is an ultimate goal of the combined professions of medicine and nursing. On the contrary, it is because this goal cannot be reached without a numerically enhanced nursing service, including specially trained massagers, far better laboratory facilities, an unlimited supply and unbridled use of expensive drugs, and, above all, more and better hospital facilities, that I propose to concentrate on how to grapple with the problem as it presents itself in average hospital and private practice in Britain to-day.

We are faced with the fact that, except in a few clinics that are accorded facilities not vouchsafed to any but a mere handful of the profession, there is not one iota of evidence that pulmonary embolus is less frequent to-day than it was ten, fifteen, or twenty years ago. It is for this reason, while continuing to preach the gospel of the prevention of phlebothrombosis instead of sitting with folded hands awaiting the medical millennium, that I propose to concentrate on measures to forestall pulmonary embolism which the clinician himself can inaugurate and carry out if he has the energy and determination to do so.

Fatal pulmonary embolus is always disconcerting. Those in attendance rightly cannot smother a conviction that the visitation should not have occurred. Little wonder that generations of conscientious workers have sought to rid the practice of surgery and gynaecology of a scourge. I envisage (a) the early detection of phlebothrombosis, and (b) the removal of the clot from the femoral vein before it has moved to the heart, as the two limbs of a Colossus astride a subject of fundamental importance to every surgical practitioner.

Early Diagnosis

The temperature chart shows unexplained repeated slight elevations. As the condition is more prone in those past the meridian of life and the highest incidence

is between ages 50 and 60 (Fig. 1), if the patient has undergone an operation about a week previously, more particularly if that operation was one of herniotomy, hysterectomy, resection of the rectum, prostatectomy, cholecystectomy, or

FIG. 1.—The age incidence of fatal pulmonary embolism. (A. W. Allen's and other statistics.)

for perforated appendicitis, and decidedly if the patient has been nursed with a pillow placed beneath the knees, the well-trained clinician's thoughts should reflexly turn to the veins of the lower extremities. While it is true that the fewer the symptoms caused by phlebothrombosis the greater the danger of pulmonary embolism, it is equally true that the majority of cases of phlebothrombosis decubiti remain undiagnosed until pulmonary embolism has occurred, *because the lower limbs have not been examined*. When all those in attendance are alert to the dangers of clotting in the veins of the legs, when the nurse reports a slight pain in the calf and, in relevant cases (especially between the third and seventh post-operative days), the clinician undertakes routine examinations to exclude phlebothrombosis, then, and then only, is real progress in the prevention of pulmonary embolism likely to occur.

Have the bed-clothes turned up (not down) and display the whole of both lower extremities. Observe the limbs for swelling, which may be slight, fullness of the veins, and a cyanotic tinge.

In suspected early cases proceed as follows:

1. Apply finger-tip pressure over each saphenous opening, and with a *stroking motion* run the finger down the course of each femoral vein, seeking a segment of unilateral localized tenderness.

2. Let the patient draw up the knees and lie quietly, relaxing the muscles. Begin by palpating the feet for tenderness, especially the medial aspect and behind the internal malleolus (Payr, 1930). Next gently squeeze the calves and then palpate the whole of the thighs systematically, the object being to seek a localized area of muscular rigidity combined with deep tenderness (Frykholm, personal communication).

3. Palpate deeply in the popliteal spaces, noting if there is tenderness here, after which ask the patient to lower the legs on to the bed.

4. Homan's sign. With the knee extended, dorsiflex the foot. Pain in the calf is a positive sign of considerable significance.

5. Compare the femoral pulses. When the femoral vein contains clot the beat of the artery alongside it is usually perceptibly weaker.

If as a result of this thorough examination the diagnosis of femoral thrombosis is reasonably assured, the advisability of exposure of the sapheno-femoral junction should receive every consideration. Removal of clot and interruption of the femoral vein will forestall many pulmonary emboli.

Femoral Thrombectomy

Femoral thrombectomy is not a new procedure. Thirty years ago Sir Carrick Robertson, of Auckland, New Zealand, successfully removed a thrombosis from the femoral vein of Mrs. Bates. In Germany, before the 1939-45 war, Kulenkampff carried out the operation many times. In the U.S.A. in recent years femoral thrombectomy has frequently been undertaken; indeed, in a number of American surgical centres the resident and nursing staffs are trained in the early detection of phlebothrombosis decubiti, and the reports on large series of cases of thrombectomy are highly satisfactory.

Anaesthesia.—I have experienced but little difficulty in carrying out the operation under local analgesia. When, as is sometimes the case, there are gelatinous adhesions between the femoral artery and vein, their separation is painful. In these circumstances, and when the patient is very nervous or grossly obese, local analgesia may be supplemented with a small intravenous injection of thiopentone.

The Incision.—A transverse incision* about 4 in. (10 cm.) long 1 1/2 in. (1.25 cm.) above the saphenous opening has proved adequate.

* Since this was written, A. W. Allen gives good reasons for choosing a vertical incision.

Operation

The inferior lip of the incision being retracted, the saphenous vein as it passes through the saphenous opening is identified and divided between haemostats. After the fascia that constitutes the edges of the saphenous opening has been slit vertically, employing the stump of the saphenous vein as a guide, the femoral vein can be quickly exposed with but little disturbance to it. That this great vein is filled with clot may be apparent at once, but clots cannot be felt unless they are of the most solid character. Employing a Watson Cheyne dissector, the femoral vein is isolated for a distance of about 3 in. (7.5 cm.), exercising gentleness for fear of displacing the clot.

The first aim is to clear the circumference of the upper end of the common femoral vein sufficiently to pass a sling (a narrow strip cut from a sheet of corrugated rubber) around it. Once the sling is in action (see Fig. 2) there is no fear of displacing the clot towards the heart, and the process of freeing the femoral vein and identifying the superficial and deep branches and other radicles can proceed apace. A sling is passed under the superficial femoral vein at the lower end of the wound. Ideally another sling should be passed under the deep femoral vein, but I have omitted this step in most of my cases. Neither the upper sling nor the lower sling is put into action at this stage. The haemostat on the stump of the saphenous vein, which has served well first as a guide and later as a tractor, is removed and the sealer's mouth of the vessel is prised open (Fig. 2); scissors are introduced and the common femoral vein is slit for about half an inch.

There is no need to become apprehensive regarding a possible haemorrhagic cascade: if the vein contains much clot there will be no bleeding at all; if it contains loose clot the very thing we want is to let the femoral vein bleed and sweep out the clot. Haemorrhage can be brought under absolute control with the slings. Be assured that with the slings in position the surgeon is complete master of the

FIG. 2.—Femoral thrombectomy. Bisection of the saphenous vein.

FIG. 3.—Clot being expressed from the femoral vein. Some of it is often extruded spontaneously.

situation at any moment. When present, clot is expressed from the distal end of the vein (Fig. 3). By the delicate use of Desjardin's gall-stone forceps a long wormlike clot can often be extruded without breaking it, or at any

FIG. 4.—Clot extractor for use with a suction apparatus. (Made by Hawkins, Ltd.)

rate not fragmenting it. The same procedure in extracting clot from the proximal end is undertaken. If free bleeding occurs the sling is tightened and the next step omitted. A glass tube or, better still, my pattern clot extractor (Fig. 4) connected to a sucker is passed up the common femoral vein into the iliac vein (Fig. 5). Smaller clots can be expeditiously removed by its agency. Ideally there should be bleeding from both ends of the vein. In my experience, when a considerable amount of clot has been extracted it is seldom realized from the distal end. The vein is clamped

FIG. 5.—Clot extractor in use.

above and below the opening that has been made into it. The vein is then divided across the ends and ligated. After sprinkling sulphanilamide powder into the wound the skin is closed with rubber dam drainage. I have not regretted draining the wound, but I have had a little trouble with local sepsis in cases where this step is omitted.

Immediate After-treatment.—Prophylactic penicillin treatment is not out of place. The limb is elevated on pillows, but the patient is encouraged to move it from the beginning. Even should there be a clot above the point of interruption of the vein the motive power that sweeps the clot to the heart is lacking, and consequently the danger of pulmonary embolism, at any rate from the iliac vein on the side operated upon, is greatly reduced. In recent cases, with the object of preventing further intravenous clotting, I have ordered the administration of dicoumarol for a week.

More Remote After-treatment.—On the third day the patient is sat out of bed, unless other considerations negate this. Before he gets up, flexible adhesive plaster, with the sticky side outwards (which permits its easy painless removal), is applied from foot to groin, so as to support the whole limb firmly.

Sequelae are surprisingly few. Astounding to relate, there is less swelling of the limb than is observed in cases of thrombophlebitis followed by spontaneous recovery. In the latter case the accepted practice is to keep the patient strictly at rest with the limb elevated for six weeks. Compare from the patient's point of view this tedium with vein interruption and sitting out of bed on the third day. Certainly there is some swelling of the limb, which continues for weeks or months; consequently it is usually advisable for the patient to wear a crêpe bandage for six months.

Less Straightforward Cases

Occasions will arise where the femoral vein is explored and clot within it is not discovered. In these circumstances it is usually advisable to explore the contralateral side, although this step requires the conviction that one is acting in the best interests of the patient. On other occasions when the patient has had a pulmonary embolism and, as always, another (probably fatal) one is feared, and there is no clear guide as to which femoral vein to explore, a most onerous decision has to be made—whether (a) to explore one femoral vein and, if that be fruitless, to explore the other, or (b) to tie up the inferior vena cava.

Ligation of the Inferior Vena Cava

The first case of therapeutic ligation of the inferior vena cava was carried out by Trendelenburg in 1911. The patient had pelvic thrombosis due to puerperal sepsis. After the operation there was dramatic improvement.

Reports of successful ligation of the inferior vena cava in cases of thrombophlebitis of the pelvic veins, and when the patient has had one pulmonary embolism and another is feared, are scattered through the surgical literature of the period between the two world wars. Contrary to what might be thought, this procedure is not a desperately formidable undertaking. It is of course essential that the ligature be applied below the level of the renal veins. To divide the inferior vena cava between ligatures appears to be a better practice than simple ligation; this would prevent late cutting through of the ligatures.

These points were brought out in and this was the impression to be gained from a paper by Wakefield and Mayo, who in 1934 were able to collect 19 cases with recovery of 15. In two instances the patient died as a result of the operation: one fatality occurred on the 23rd day, and was due to the ligature cutting through the vein; in the other case the ligature had been tied above the right renal vein.

During the past few years so much confidence has accrued in America in this to many of us still desperate expedient that in 1947 Veal *et al.* of Washington were able to present 30 cases of their own. In 28 of these the operation was undertaken on account of pulmonary embolism. Of the three deaths following the operation, two occurred in patients suffering from cardiac disease and one was due to pneumonia. It should be noted particularly that no further embolism occurred in any of the cases. So it comes about that there is reason to believe that ligation of the inferior vena cava is a practical proposition likely to save life when employed in appropriate cases at the right time. The difficulty is to be sure that the procedure is indicated. When facilities exist, intravenous injections of diodone into an exposed saphenous vein and subsequent radiography will display information regarding thrombosis of the great veins of the pelvis. The technique of the procedure is set out by Stowers and Grossman (1946).

This is not the place to enter into the technique of ligation of the inferior vena cava. It suffices to say that the operation is well within the competence of the average general surgeon, and the best surgical approach appears to be an extraperitoneal one, very similar to that of exposure of the lower end of the ureter.

Ligation of the inferior vena cava does not produce more than slight disability—oedema of the lower limbs—and this usually passes off in time.

Conclusions

At the present time in Britain there are but few surgeons who have carried out femoral thrombectomy; indeed, the operation has received less attention than pulmonary embolectomy. The latter is a heroic measure requiring

special facilities, special instruments, and special skill. Femoral thrombectomy requires none of these things.

The indications for femoral thrombectomy are: (1) when pulmonary embolism has occurred and mercifully the patient is yet in a fit condition to withstand operation, and (2) when phlebothrombosis decubiti has been diagnosed with some precision.

To endeavour to stimulate surgeons, house-surgeons, and practitioners to undertake a careful clinical examination for phlebothrombosis in relevant cases is my main object in writing this paper.

TREATMENT OF THYROTOXIC HEART DISEASE BY METHYL THIOURACIL

BY

W. E. CLARKE, M.B., M.R.C.P.

Medical Registrar, Charing Cross Hospital;
 Clinical Assistant, Cardiological Department,
 London Chest Hospital

While thiouracil has been employed in large numbers of cases of thyrotoxicosis, comparatively little attention has been paid to its use in the cardiovascular complications of that condition. It is the purpose here to survey this aspect of thiouracil therapy. Case histories are recounted, and these are reviewed in the light of the literature.

Patients suffering from cardiovascular disease to whom thiouracil may be administered may be grouped broadly into those in whom cardiovascular disease results from thyrotoxicosis and those in whom it originates independently. In the latter group thiouracil therapy has the same rationale as thyroidectomy has had in the past—that is, a lowering of the basal metabolic rate. It has been given with this aim chiefly to patients with angina pectoris and those with congestive heart failure.

Thyrotoxicosis is a common disorder, but few cases nowadays develop cardiovascular disease: timely operations have in so many instances remedied the condition in an early phase. Nevertheless, most of the published series of cases of thyrotoxicosis have contained several examples of such complications as auricular fibrillation. Thus Himsworth (1944) notes two cases of auricular fibrillation in 33 cases of hyperthyroidism. Grainger et al. (1945), reporting 29 cases of thyrotoxicosis, mentions two cases of patients with auricular fibrillation who reverted spontaneously to normal rhythm after treatment by thiouracil. Nussey (1944) mentions four cases of auricular fibrillation in a series of 29 cases of thyrotoxicosis. McGarack et al. (1945) reported the effect of thiouracil on 18 cases of auricular fibrillation in a series of 78 cases of thyrotoxicosis. Cookson (1945) mentions 10 cases of auricular fibrillation in 66 cases of thyrotoxicosis, and more recently Cookson and Staines (1947) reported eight patients out of 16 with

auricular fibrillation who reverted to normal rhythm. Wilson (1946) noted six cases of auricular fibrillation in 66 cases of thyrotoxicosis.

The material in the present series comprises 10 patients with cardiovascular disease associated with thyrotoxicosis—seven women and three men, whose ages ranged from 41 to 81. The longest history of symptoms was eight years, the shortest a few weeks. The increase in basal metabolic rate ranged from +14 to +55%, and the lowest blood cholesterol before treatment was 106 mg. per 100 ml. There were six cases of nodular hyperplasia and four cases of diffuse enlargement; the type of enlargement did not affect the response to treatment. They have been observed over a period of 8 to 18 months.

In four patients with established auricular fibrillation various complications caused failure in each case. There were two patients with paroxysmal auricular fibrillation, in both of whom treatment was successful. Of the two patients with hypertension and cardiac enlargement one showed only slight improvement, the other none. Striking improvement resulted in the patient with angina of effort, who was able to resume work after being completely incapacitated. One patient with premature contractions and gross diminution of cardiac reserve was much improved, and was able to do her housework.

Case Histories

Case 1.—A man aged 41 was diagnosed as suffering from thyrotoxicosis in 1940. In April, 1946, auricular fibrillation began. When seen six weeks later he showed typical thyrotoxic signs and symptoms. The thyroid was diffusely enlarged. There was no cardiac enlargement or any sign of valvular disease. Auricular fibrillation was present; the heart rate was 120 and the blood pressure 130/70. There was no cardiac failure. The basal metabolic rate was +45% and blood cholesterol 155 mg. per 100 ml. On methyl thiouracil therapy the B.M.R. fell to -10% and the blood cholesterol rose to 283 mg. Cardiac rhythm was restored to normal by 50 gr. (3.2 g.) of quinidine two weeks after starting thiouracil administration. After eight months methyl thiouracil had to be withdrawn because of granulopenia. The patient continued at work, against advice, from February to June, 1947, during which time he took sedatives, and then agreed to thyroidectomy. He has since been quite free from symptoms, the heart remaining in normal rhythm throughout.

Case 2.—A man aged 68 presented with sacral pain following an infected pilonidal sinus. On examination he was thyrotoxic, with slight exophthalmos and a nodular goitre. Auricular fibrillation was present. The heart rate was 124 per minute; the blood pressure 185/90 and there was marked arteriosclerosis. The heart was enlarged and the sounds weak; there was no evidence of valvular disease. He made steady improvement on methyl thiouracil for three months, when obvious chemosis and exophthalmos developed. He was admitted to hospital and treated with Lugol's iodine and 200 mg. of di-iodotyrosine daily; later, deep x-ray therapy to the pituitary gland was given. In two months the right eye developed an exposure keratitis and hypopyon, necessitating evisceration. After a very stormy convalescence he recovered, and eventually was discharged, still with fibrillation between 80 and 90 a minute and a blood pressure of 170/90.

Case 3.—A woman aged 46 presented with nervousness, depression, palpitations, and occasional irregularities of the heart. When seen in 1946 she was thyrotoxic and had an adenoma of the right lobe of the thyroid. There was no congestive failure; fibrillation was present at 140 a minute, with a radial pulse deficit of 16 a minute. Blood pressure was 130/80. Screening showed a typical heart of mitral stenosis. The electrocardiogram revealed auricular fibrillation with right ventricular stress. She made a good response to methyl thiouracil therapy, but on her return home various functional symptoms supervened and she decided to undergo operation.

Case 4.—A frail old lady of 81 presented with thyrotoxicosis and general slight thyroid enlargement. There was no cardiac

failure; rhythm was regular and blood pressure 205/100. X-ray examination revealed left ventricular enlargement and a prominent sclerotic aorta, with hilar engorgement. She was put on methyl thiouracil and after 13 days had improved somewhat; but she then developed drug fever to 103° F. (39.4° C.), which disappeared in 24 hours on stopping the methyl thiouracil. One week later fibrillation was noticed; at first it was intermittent, but in two days it had become persistent. Her condition deteriorated rapidly; she developed pneumonia, and died in coma two weeks later.

Case 5.—A woman aged 65, after a shock in December, 1945, noticed lack of energy and dyspnoea on effort, and later some swelling of the ankles. On examination she was thyrotoxic, with slight general thyroid enlargement. There were a few rales at the lung bases, the liver was enlarged by three fingerbreadths, and there was slight peripheral oedema. There was fibrillation on her first visit; but later the heart was regular at 96. It was not enlarged, and there was no valvular disease. Blood pressure was 150/80, with obvious arteriosclerosis. On methyl thiouracil she made excellent progress, which is being maintained on very small doses.

Case 6.—A woman aged 55 gave a history of prominence of the eyes and dyspnoea for 18 months, and palpitations for six months. On examination bilateral proptosis was present. The pulse was regular at 76, the blood pressure 150/95. There was a slight thickening of both lobes of the thyroid, but no thyrotoxicosis. On July 15, 1946, the blood cholesterol was 225 mg. per 100 ml. Radiographs of the pituitary fossa were normal. On Sept. 9 she was given hexoestrol, and two weeks later she presented with exophthalmos, enlargement of the thyroid, and thyrotoxicosis. Fibrillation was present. She responded rapidly to methyl thiouracil therapy, and the heart reverted spontaneously to normal rhythm.

Case 7.—A woman aged 52 gave a long history of nervous symptoms, which were exacerbated by the outbreak of war. In January, 1943, the thyroid was noticed to be enlarged. In July, 1946, she complained of lassitude, dyspnoea on effort, and palpitations. On examination she was thyrotoxic, and an adenoma of the right lobe of the thyroid was found. The heart was slightly enlarged, rate 90 a minute, and the blood pressure was 220/115. The arteries were normal for her age. She improved generally on thiouracil therapy, but her blood pressure fell only to 180/100.

Case 8.—A woman aged 60 gave a three-year history of loss of weight and excitability. On examination she was thyrotoxic and had a general nodular enlargement of the thyroid. The heart was slightly enlarged, with a soft apical systolic murmur. The blood pressure was 165/90, with general arteriosclerosis. The B.M.R. was +55% and the blood cholesterol 129 mg. per 100 ml. After seven days on methyl thiouracil (total dosage 4.6 g.) her temperature rose to 103.6° F. (39.8° C.). The next day fibrillation started, and continued for five days, remitting spontaneously. Thyroidectomy was performed later with excellent results. Her blood pressure, however, remained unchanged.

Case 9.—A man aged 45 had a coronary thrombosis in March, 1945, while in the Army, and was in hospital for three months. This was followed by angina of effort even on slight exertion. In May, 1946, paroxysmal nocturnal asthmatic attacks developed and he had to give up his work. Dyspnoea on effort was increasing, with ankle oedema in the evenings. In November, 1946, typical thyrotoxic symptoms started. On examination then he was obviously thyrotoxic. The thyroid was firm and easily palpable. The heart was not enlarged, and rhythm was regular at 120 a minute; there was no failure. Blood pressure was 145/90; arteriosclerosis was present. The B.M.R. was +39%, and the blood cholesterol 106 mg. Thiouracil therapy resulted in great improvement. He is now back at work, and has only a very mild chest pain after moderate effort.

Case 10.—A woman aged 45 had had increasing dyspnoea on effort for nine months, and when seen in July, 1946, could walk only a short distance on the level. She was thyrotoxic, with nodular swelling of the right lobe of the thyroid. There was no failure, the heart was not enlarged, and there was no valve affection. Pulse rate 100, with frequent premature con-

tractions. Blood pressure was 145/70; the arteries were normal for her age. She improved on thiouracil, and manages her housework and has no cardiac symptoms. She is still on 50 mg. of methyl thiouracil daily.

Comments on Results

Auricular Fibrillation.—In the present series six patients had established or paroxysmal auricular fibrillation. Three reverted to normal rhythm; two of these were suffering from paroxysmal auricular fibrillation and in one it had been established only a few weeks. The latter patient developed a granulopenia, and treatment had to be abandoned; but normal rhythm was held, and continued after thyroidectomy. In McGarack's (1945) series there were 18 cases of auricular fibrillation; 12 of these reverted to normal rhythm spontaneously on treatment with thiouracil, and three others were successful when digitalis was given. In none of these cases was there any other cardiovascular disease, the fibrillation being due entirely to the thyrotoxicosis. In Cookson's (1945) cases normal rhythm was restored in three out of 10 cases of auricular fibrillation. Of the remaining seven, one was treated only six days before death, and one also had mitral stenosis. In Wilson's (1946) series five out of six cases of auricular fibrillation reverted to normal rhythm spontaneously, and here again no other cardiac lesion was mentioned. Similarly Grainger's two cases reverted to normal rhythm spontaneously. Of Nussey's four cases two were restored to normal rhythm—one spontaneously and one after the administration of quinidine. In the other two, of one an five years' standing, no attempt was made to restore normal rhythm.

Hypertension.—Grainger *et al.* (1945), noting the effect of thiouracil on hypertension not associated with thyrotoxicosis, found that little or no response occurred. Two of our cases had hypertension as the only cardiovascular abnormality and two more had established auricular fibrillation with hypertension. Of the first two, one responded well so far as her toxic symptoms were concerned, but showed only a slight fall in blood pressure. The other developed a drug fever, and treatment had to be abandoned. Thyroidectomy was performed; her blood pressure, however, remains at its former level. Of the other two, one developed malignant exophthalmos, and his fibrillation and hypertension persisted; the other reverted to normal rhythm, but the blood pressure rose from 150/95 to 170/9.

Angina.—One patient with angina pectoris gave an excellent response to thiouracil. The toxic symptom completely disappeared, and instead of an attack of angina pain occurring after walking half a mile (0.8 km.), he now hardly troubled during the whole day. Raab (1946) states that the treatment of angina pectoris unassociated with thyrotoxicosis proved effective in seven out of 10 cases. The clinical improvement coinciding closely with the fall in the basal metabolic rate. Ben-Ascher (1947) found thiouracil beneficial in 25 out of 37 patients with angina pectoris. In a former paper Ben-Ascher (1945) reported on eight cases of angina pectoris with favourable result in all of them. The basal metabolic rate fell from -8% to -20% at the time of the maximum improvement. Di Palma and McGovern (1946), however, reporting eight cases of angina pectoris, found that treatment had to be abandoned in four instances, and two of the others became myxoedematous. One patient had symptoms of coronary occlusion during treatment.

Cause of Failure of Thiouracil Therapy.—Failure in five cases in the present series was due to a variety of reasons. In two cases drug fever prevented further administration. In another, psychological inability to face the long treatment necessary in thiouracil therapy was the cause, and

one was due to development of granulopenia while on a maintenance dose of thiouracil. One patient developed a malignant exophthalmos which necessitated evisceration of an eye.

Thiouracil Therapy v. Surgery

Thiouracil interferes with the production of thyroxine by the thyroid gland and, as shown by Himsworth *et al.* (1947), after the first three weeks there is no difference between the condition of patients so treated and those treated by thyroidectomy; and the risk of thyroidectomy is removed. With expert surgeons the mortality rate is 1% or less, and is probably nearer 4-5% when overall figures are taken. *A priori*, in cases with cardiovascular disease complicating thyrotoxicosis the figure is higher. In patients who refuse operation outright thiouracil provides an effective alternative method of treatment.

Thiouracil may also be used to assess the effect of thyroidectomy on the cardiovascular condition generally, and to bring the patient into a better state pre-operatively. This is so especially in cases in congestive heart failure. It is given for at least three weeks; it is then stopped seven to 10 days before operation, and iodine is substituted. This reduces the friability and vascularity of the gland resulting from the use of thiouracil, and substantially facilitates the surgical procedures. In patients who are sensitive to iodine, however, thiouracil may be used alone as a pre-operative measure.

Thiouracil may be used in the younger age groups in whom auricular fibrillation has occurred secondarily to the thyrotoxicosis alone. The heart in most cases will revert to normal rhythm spontaneously, and almost all of those which do not will do so when quinidine is combined with thiouracil therapy. The thyrotoxicosis may remit in time, and after adequate treatment over 12 to 18 months the thiouracil may be stopped with a fair chance of complete recovery.

Whenever thiouracil is used the risk of allergic or toxic complications arising is very real. The drug is stored in the bone-marrow in concentrations up to 16 times that in the blood, and it is this which causes the most lethal of all the ill-effects attendant on its use. Fowler (1946) has shown that of 1,573 cases collected from the literature toxic reactions of one kind or another occurred in 13.7% and serious complications in 4%; the mortality was 0.57%, and was decreasing. With the smaller doses needed when using methyl or propyl thiouracil complications are less likely to occur.

In cases with rheumatic, hypertensive, or arteriosclerotic heart disease neither thiouracil nor thyroidectomy will have any effect on the original heart condition. It will, however, improve prognosis by removing the toxic effect and the added load imposed on the already damaged heart by the thyrotoxic state.

Some cardiologists of repute have entirely abandoned the use of thiouracil as being too toxic and dangerous, and regard thyroidectomy as an equally safe method of treatment, with a more immediate and better cosmetic result.

Thiouracil should never be used when the gland is so enlarged or so placed as to cause tracheal obstruction; nor in cases in which there is the slightest suspicion of malignancy. In elderly people thyroidectomy is to be preferred. There is always a possibility of relapse on ceasing treatment or of complications, and such people will then be in a worse condition for thyroidectomy and their myocardium less well able to withstand either operation or thyrotoxicosis. In those whose temperament or economic condition will not permit them to face the long treatment with thiouracil under adequate supervision thyroidectomy is best performed at once.

Summary

An account is given of the use of methyl thiouracil in 10 patients with thyrotoxic cardiovascular disease.

The value of this treatment in auricular fibrillation, hypertension, and angina pectoris is discussed and the results are compared with those of other observers.

Treatment failed in five cases, the causes of failure being drug fever (2), malignant exophthalmos (1), granulopenia (1), and neurosis (1).

The considerations governing the choice between surgical treatment and thiouracil therapy in thyrotoxic cardiovascular disease have been reviewed.

I am much indebted to Dr. K. Shirley Smith for his encouragement and help and for permission to refer to his cases; also to Dr. H. A. Dunlop for permission to include two of his patients in this series.

PENICILLIN AND GONORRHOEA

AN ANALYSIS OF 150 CASES TREATED BY THE SINGLE-INJECTION METHOD

BY

C. C. R. DOWNING, M.A., M.D. Cantab.
 Medical Officer in Charge of Male V.D. Clinic,
 Cardiff Royal Infirmary

It is now common knowledge that penicillin injected intramuscularly affords the best means of curing gonorrhoea. Like other treatments it has, however, certain disadvantages, and an analysis of 150 cases seen at the male V.D. clinic of the Cardiff Royal Infirmary may prove of interest. The cases were treated between October, 1946, and June, 1947. All except three showed typical signs and symptoms of acute gonococcal urethritis. In each case the diagnosis was confirmed by a microscopical examination of the discharge.

Details of the Cases

Their nationality was: British, 144; Greek, 3; Maltese, 3. 101 were single, 44 married, 3 married but separated, and 2 were widowers.

		Age Incidence	
16-20 years	9	36-40 years 8
21-25 "	50	41-50 " 7
26-30 "	44	51-60 " Nil
31-35 "	31	61-70 " 1

The greatest number of cases occurred during the age group 21-25, and altogether 125 out of the 150 men were from 21 to 35 years old. The youngest patient seen was a boy aged 16 years and 11 months whose case is described below, and the oldest was a widower aged 63, who gave a history of having had gonorrhoea, 30 years previously. This man was first seen on Nov. 11, 1946, after infection by a prostitute. He was free from discharge and other signs of gonorrhoea in 10 days after one injection. He then ceased attending. On Jan. 2, 1947, he returned, admitting to further coitus, and was found to have become reinfected. Again a single injection of penicillin cleared

him up. He then absented himself once more, only to reappear with a further infection on April 21. Thirty-five of the men were on demobilization leave. The rest were clerks, dock labourers, farm workers, seamen, and every conceivable type of worker found in a large seaport town. The sources of infection were: by friends, 60; by prostitutes, 56; marital coitus only, 4; risks denied, 2; not stated, 28. These figures show what is already widely known—that the prostitute is not the only source of infection.

Duration of Infection before Treatment

1 week and under	..	50	Between 1 and 2 months	..	1
Between 1 and 2 weeks	..	55	2 " 3 "	..	1
" 2 " 3 "	..	26	Over 3 months	..	2
" 3 " 4 "	..	6	Uncertain	..	9

The great majority of the men came to the clinic within two weeks of becoming infected. In the "uncertain" group were a number of sailors who had had treatment with ineffectual remedies on board ship. No doctor was on board to give them proper advice.

All the patients showed typical signs and symptoms of acute gonococcal urethritis, with the exception of the following three:

1. A man aged 31, who had had gonorrhoea while on active service in India in 1944. He said he had been cured. No gonococci were found in a specimen of pus which looked typical of a gonococcal infection. He had been married two years and denied extramarital coitus. He made an uneventful recovery after one injection of penicillin.

2. A Chinese cook on board ship aged 34, who had been given an unknown dose of sulphapyridine by the ship's steward. No obvious discharge was present. He was given one injection of penicillin and a "V.15" as he was going to sea again.

3. A man aged 34, who had a primary sore as well as gonorrhoea. He was given 20 g. of sulphathiazole concurrently with arsenic and bismuth injections. After 10 days he was given an injection of penicillin, as his discharge had not gone. It did so in a day or two after the penicillin. He is still under treatment for syphilis.

There were four cases of double infection: two had a typical primary sore as well as an acute gonococcal urethritis, and two proved to be double infections but the onset of the syphilitic infection was delayed by the penicillin. Reports of these two cases follow.

Onset of Syphilis Delayed by Penicillin

Case 1.—A married man aged 24, with no previous history of venereal disease, was first seen on Sept. 30, 1946. He had run risks a week before, and had had a urethral discharge for three days. It was a typical example of gonococcal urethritis, and cleared up completely after one injection of penicillin. He reported at proper intervals of time, and on Nov. 4 his Wassermann reaction was negative. At about 12 noon on Nov. 21 I noticed a small plaque-like swelling on the body of the penis bordering on the coronal sulcus. It had a tiny central pinpoint opening. By Nov. 28 it was a typical indurated hard sore. Dark-ground illumination failed to reveal spirochaetes, but his Wassermann reaction was ++ on Dec. 9. He had typical enlarged inguinal glands on both sides. He was at once given treatment, and is still attending. This would appear to be a delayed chancre. The man first noticed a spot on his penis about Nov. 20, thus the first appearance of a specific lesion was approximately 51 days after the date of infection.

Case 2.—This patient, a married man aged 26, was first seen on Oct. 14, 1946. He had been infected a week previously and discharge had been present for three days. He had a typical gonococcal urethritis. The discharge dried up in a week after one injection of penicillin. On Dec. 2 his Wassermann reaction was negative; on Feb. 3, 1947, it was + ± —, and on Feb. 10 it was + + +. The only physical signs of syphilis were very typical enlarged inguinal glands on both sides. There was no trace of any primary sore, and the man was not aware that he had seen anything like a pimple on his

penis. He is now being treated with concurrent injections of arsenic and bismuth. The first evidence of syphilis appeared approximately 112 days after the date of infection.

Reinfections.—During the period September, 1946, to June, 1947, there were 17 patients who reappeared with a fresh infection of gonorrhoea—12 admitted the fact spontaneously; the other five, when pressed and confronted with a pathological report, left little doubt in my mind concerning the source of their acute urethritis.

Type of Penicillin Used, Dosage, and Technique

Two penicillin oil-wax suspensions (ethyl oleate and arachis oil) were used, and both proved very satisfactory. They were warmed up to blood heat and well shaken before being drawn up into the syringe. The dose given was 375,000 i.u. in each case. It was injected into the upper and outer quadrant of the buttock. None of the patients complained of more than temporary pain or stiffness at the site of injection. No time was lost at work and no patient had any allergic reaction. The discharge disappeared in most cases very quickly: 41 were free of discharge in under 1 week, 66 in 1 week, 5 in 2 weeks, 3 in 3 weeks, and 5 in 4 weeks. In 30 cases no definite time was stated.

Sulphathiazole tablets were prescribed in 5 cases in which the urine showed persistent pus cells but no gonococci after the penicillin injection. Irrigation of the urethra was not resorted to. In cases with balanitis and some phimosis a solution of 1 in 10,000 potassium permanganate was used for subpreputial lavage.

A single injection was given to 134 patients, 14 required two injections, one patient three, and another four. When two injections were needed, the patients failed to attend promptly after the first one. The period varied from one to four weeks, and purulent discharge was always present. In one case the discharge had cleared up completely in a week, only to recur three weeks later. I have a suspicion that it was a case of reinfection, although this was denied. The case requiring three injections is described below (Group 3, Case 1).

Case Requiring Four Injections.—This patient had had gonorrhoea in 1940 during his Army service and had been cured. He was admitted with an acute gonococcal urethritis and penicillin was injected. When he attended the clinic three weeks after the injection the discharge was still profuse. A second injection was given. This time he stayed away for five weeks, and when he reappeared the discharge was as free as ever. A third injection was given. Again he absented himself, this time for 10 weeks. Then on examination the discharge was still plentiful, and a fourth injection was given. Since then he has not attended.

End Results

Group 1.—This group consisted of 62 men who were discharged cured. No patient was under treatment at surveillance for less than three months. The average period of treatment for the whole group was about four months per patient. Every one of them was free from all signs and symptoms of gonorrhoea and, except in one case in which a double infection was present, the Wassermann reaction was negative. Tests of cure adopted conform to those advised by the Ministry of Health.

Group 2.—This group consisted of 56 men who had attended the clinic for less than four weeks and had then ceased attending. Twenty-five came only once, so it is impossible to say whether they were properly cured. It is not unreasonable to assume that at least their discharge were dried up. All the remainder were dry and free from signs and symptoms.

Group 3.—In this group of 30 patients who ceased attending after one to seven months only the following three showed any signs of infection.

Case 1.—The patient, aged 23, was infected two weeks before. He attended the clinic on four occasions between Dec. 23, 1946, and March 3, 1947. On admission he was found to have a typical gonococcal urethritis and penicillin was given. He absented himself for a month, and when he returned he was found to be still discharging freely. A second injection of penicillin was given, and he then disappeared for a further month, only to return again with a right-sided epididymitis and orchitis. A third injection of penicillin was given, followed by a course of sulphathiazole. When he turned up a fortnight later his discharge had gone and his testicle was less swollen though still tender. Since that time he has ceased attending altogether.

Case 2.—A youth aged 16 years 11 months had a typical gonococcal urethritis associated with phimosis and balanitis. He did not attend until two weeks after his first injection, and was then showing much purulent discharge. The second injection of penicillin cleared up the gonococcal inflammation of the urethra, but he still had a mild degree of balanitis. This showed no evidence of being gonococcal. He ceased attending after 11 weeks' treatment.

Case 3.—A man aged 31, who had served in the Army in the East, attended for 10 weeks, and when he ceased attending had been free from discharge for a long time. His urine, however, still showed some pus cells. His general health was poor. He had been a prisoner of war in Japanese hands and had had pellagra, beriberi, and dysentery.

Group 4.—The following two cases are still attending at the clinic.

Case 1.—A man aged 21 had typical gonococcal urethritis. The discharge and all other signs and symptoms cleared up in 24 hours. His gonococcal flocculation reaction, however, was positive.

Case 2.—A man aged 26 had had gonorrhoea in the early part of 1946. He had a typical gonorrhoeal discharge, which cleared up in a week after an injection of penicillin. His urine still shows some pus cells.

Comments

To analyse case records at a V.D. clinic is difficult and unsatisfactory. In the first place I feel that the patients' statements are often open to doubt. In the second place—and this is the main trouble—such a large percentage of patients cease attending before their surveillance is complete. However, from the facts and figures that emerge from this analysis I can say that penicillin given intramuscularly in an oil-wax suspension is the treatment of choice for gonorrhoea to-day. Its advantages are obvious. Easy to give, it causes no appreciable pain or discomfort. The patient is asked to spend the minimum amount of time attending the doctor and loses no time at his work. His discharge is quickly dried up, and if he co-operates he is certain of a quick cure. It is to be specially noted that complications such as orchitis, epididymitis, and vesiculitis are now very rarely met with.

As I said at the start, there are a few disadvantages: (1) It is almost too efficient. The patient gets well so quickly and so easily that some are tempted to run further risks. No longer is the cure worse than the disease. (2) As is already known, penicillin can mask and delay the onset of primary syphilis. (3) Because of this the necessity for repeating the Wassermann test over a period of months is unfortunate. So many patients fail to realize the importance of having more than one blood test.

I would like to express my thanks to my colleagues, Dr. H. Sheasby and Dr. J. Rebeiro, for their help in preparing this paper, and also to acknowledge much assistance given me by Mr. R. D. Vanstone, the clerk to the clinic.

Medical Memoranda

Penicillin, Beeswax, and Allergy

The following two cases of allergy occurring in general practice are described to illustrate the severity of reaction to penicillin and the possibility that some component of the beeswax-oil suspension, other than the penicillin, was the exciting factor.

CASE 1

A man aged 58 complained of persistent boils, and as no previous treatment had allayed the condition it was decided to give a course of penicillin. Injections of 250,000 units in distilled water were given twice daily on June 16 and 17, 1947, and one on the 18th. The patient then defaulted. However, the furunculosis improved considerably.

On June 25, the ninth day after the first injection of penicillin, I was asked to see the patient. He stated that while driving home that day he had felt itching, first of the left foot where his boot-laces pressed, and then of the right foot in the same situation. He felt very drowsy and could hardly keep awake to drive the car home. Within half an hour he began to itch all over. He also complained of severe pain behind the sternum and of severe indigestion. An examination showed the body to be covered with large urticarial weals about the size of the palm of the hand. The feet, hands, and face were swollen. This condition persisted for seven days in spite of treatment with "benadryl," 50 mg. thrice daily, later increased to 100 with adrenaline, 10 min. (0.6 ml.), twice daily. After seven days the condition gradually subsided, but during this time the itching was intense and the patient had only very fitful sleep with the aid of morphine.

CASE 2

The patient, aged 33, was the wife of an ardent bee-keeper, and she helped with the manipulation of the bees from time to time. At first the patient had little reaction to stings until the summer of 1941, when she was stung on the lip. This became very badly swollen. In the summer of 1944 she was stung on the leg. The leg became very swollen, and she stated that the sites of previous stings also became swollen. In February, 1947, she had a small carbuncle on the face, which was treated with penicillin, 150,000 units, in distilled water, given eight-hourly for five days. This cleared up the carbuncle. On Oct. 25 a carbuncle began to develop on the chin, and next day injections of 250,000 units of penicillin in wax-oil suspension were started. These were given twice daily into each buttock alternately at the "site of election." The injections were continued until the morning of Oct. 29, six injections in all being given. On Nov. 2, the eighth day after the first injection of penicillin, the patient began to feel the site of the old bee-sting on the leg itching and a weal developed. Within half an hour the sites of injection of penicillin on both buttocks became itchy and red. For a week the sites of the injections were covered with a ring of urticaria and there was considerable swelling of the underlying tissues. During the same period the site of the old bee-sting on the leg was irritated and became swollen from time to time. The patient also averred that the taking of hooley led to an increase in the local symptoms of allergy shortly thereafter. All symptoms were controlled to some extent by benadryl.

COMMENTARY

Case 1 is described to illustrate the severity of the allergic reaction to penicillin. The patient avers that he had never before had penicillin in any form whatsoever.

The second case is the more interesting in that it would seem more likely that the local allergic reactions were due to some component of the beeswax suspension. This is deduced from the facts that the bee-sting on the leg was re-activated. The other interesting factor is that the patient was quite definite that the ingestion of section-boney caused an increased irritation of both the site of the bee-sting and the sites of penicillin injection. It may be argued that the sting of a bee has no relation to beeswax. The firm which produced the beeswax was contacted. They stated that the beeswax used in the suspension is the natural product, but that in their opinion it is impossible for formic acid or other component of a bee-sting to be present in the wax. On the other hand, a well-known naturalist, who is also a bee-keeper, is of the opinion that it is quite possible for formic acid to be present in nectar and that natural beeswax could quite easily be polluted with nectar.

Reviews

MORE LIGHT

Light, Vision and Seeing. A Simplified Presentation of Their Relationships and their Importance in Human Efficiency and Welfare. By Matthew Luckiesh, D.Sc., D.E. Fourth printing. (Pp. 323; illustrated, 25s.) New York: D. van Nostrand Company, Inc. London: Macmillan and Co. 1947.

Matthew Luckiesh, the Director of the Lighting Research Laboratory of the General Electric Company of America, is a prolific writer, and this book, which is represented as "a simplified presentation of the relationships of light, vision, and seeing and their importance in human efficiency and welfare," conforms to the usual pattern of his writings. It is a simple and popular exposition of the importance of adequate lighting in everyday tasks and in industry. The author traces the history of commercial illumination from the candle to the fluorescent tube, discusses the workings of the visual apparatus, points out the meaning of visual acuity and its dependence on illumination and contrast, and shows how lighting is measured and how, when it is adequate, it eases ordinary work and is a potent factor in the attainment of efficiency, safety, and clear seeing.

Luckiesh has always been and still remains an enthusiast, and the book should be read with this in mind. To him the slogan "Better Light—Better Sight" (which, born in America for a nation-wide campaign, "has crossed the seven seas and invaded the five continents" and "has rapidly evolved into a world-wide movement") is a cure for all ills. That adequate artificial lighting is of the greatest importance to a civilization which has gone indoors no one will deny, but some of Luckiesh's statements—particularly those on medical questions—must be accepted with reserve. He is greatly worried, for example, by the "appalling prevalence of eye defects," but to expect engineering accuracy in an organ of the body is to misunderstand the whole economy of living organisms. Nearly all babies, he says, are born with normal vision, while one in four has measurable eye defects (especially myopia) when leaving school, due in part to eye-strain, which is preventable by good lighting. The defectives increase to 50% at middle age and to 80% at 60 years, for presbyopia (he claims) cannot rightly be accepted as inevitable. Moreover, since these defects are hereditary according to the philosophy of Lamarck, which he adopts without reservation, the penalties of the "unforgivable abuse" of our eyes with inadequate illumination are passed on to future generations. Should this abuse not be stopped (by adequate illumination), all mankind is "travelling the road towards blindness." If enthusiasm wins a case, Luckiesh should certainly make converts.

STEWART DUKE-ELDER.

PARATHYROIDS AND KIDNEYS

The Parathyroid Glands and Skeleton in Renal Disease. By J. R. Gilmour, M.R.C.P. Oxford Medical Publications. (Pp. 157; 26 figures, 18s.) London: Geoffrey Cumberlege (Oxford University Press), 1947.

This admirable and painstaking study is based on 90 cases of renal disease, with special reference to the histology and weight of the parathyroid glands and the skeleton. The author's earlier studies have enabled him to make an accurate comparison with a normal series. He divides the histological appearances of the parathyroids into six types, of which Type I is normal, and reaches the conclusion that two (II and IV) of these are due to renal disease. Of the others, III is doubtful and V and VI are not due to renal disease. Bright's disease (which he classifies according to Russell's ideas) is associated with Type IV. The author discusses the converse of his main thesis—the renal changes which may be secondary to parathyroid disease—and concludes that not only metastatic calcification of the kidney but chronic progressive nephritis may be symptomatic of von Recklinghausen's disease.

It should not be regarded as derogatory to observe that this book makes stiff reading. It is a mine of information, but

surface working of the mine is impossible. The exposition is so concentrated that any adequate summary would be almost as long as the 157 pages of the original. Perhaps that is why the author's summary seems rather inadequate and at the same time Olympian.

RAYMOND GREENE.

DETOXICATION

Detoxication Mechanisms: The Metabolism of Drugs and Allied Organic Compounds. By R. T. Cwyn Williams, Ph.D., D.Sc. (Pp. 288, 25s.) London: Chapman and Hall, Ltd. 1947.

The versatility and resource of the animal mechanism are well shown in the variety of ways in which it disposes of alien substances. This metabolic strategy, popularly known as detoxication, has been recognized for a century, but only recently is becoming specially prominent—in relation to modern chemotherapy. Dr. Williams, known for his contributions to the chemistry of the glucuronides, has now surveyed the wide field of detoxication processes and mechanisms in a closely written yet lucid monograph which, though the index contains some 1,500 entries, is no mere directory but a systematic exposition of a fascinating subject.

Detoxication, or, as it might be termed, *para-metabolism*, is of primary interest to the biochemist in that it presents Nature with chemical posers to solve. The pharmacologist, knowing the chemical tactics of the organism, can construct new drugs or modify old ones so as to prolong their action, enhance their potency, or repress their toxic qualities. The industrialist, faced with the risk of chemical hazards, can learn how to recognize their signs and avoid their consequences if he knows the detoxication capacities of the workers. Perhaps in his next edition Dr. Williams will criticize the work of Ekman (1944) on the effect of ascorbic acid on the metabolism and excretion of cyclic compounds, which should be capable of extension to several types of detoxication processes. Meanwhile we have ample material to occupy our attention in his excellent book, which will interest and enlighten many readers and will provoke discussion and encourage experiment.

W. R. FEARON.

PSYCHOTHERAPY IN PRISONS

Handbook of Correctional Psychology. Edited by Robert M. Lindner, Ph.D., and Robert V. Seliger, M.D. (Pp. 691, \$10.00.) New York: Philosophical Library, Inc. 15 East 40th Street, N.Y. 16.

The editors of this compendium aimed to provide a source book of techniques and methods for the treatment of the medico-psychological problems encountered in prison inmates, and there is no doubt that they have produced a useful volume. Much practical experience is summarized on such topics as court procedures, problems in the handling of special groups—for example, the female defective, sex offenders, malingerers, and juvenile delinquents—and the use of certain diagnostic and therapeutic methods such as psychological tests, the electroencephalograph, group treatment, individual psychotherapy, hypno-analysis, narco-analysis, and electric convulsion treatment. Some theoretical considerations such as the concept of the psychopathic personality, the meaning of punishment, and psycho-analytic contributions to the understanding of the criminal are also discussed. The fact that there are 47 chapters of which almost all are by different authors inevitably results in a good deal of repetition of general principles. The reader may be puzzled by the inclusion of chapters on general medicine and on some of the medical specialties—for example, eye, ear, nose, and throat, venereal diseases, the use of sedative measures in mental hospitals, and the understanding and management of gastric neuroses—which have little specific reference to prison practice.

A collection of contributions by a large number of experts has become fashionable in scientific literature. We should like to see this form of collaboration supplemented by volumes written by groups of experts in a wide range of subjects working together through the main problems in order to assess what is really known and what is not. Bergler makes this point forcibly in his lively and stimulating chapter when he states that with the insignificant scientific status of present clinical knowledge

only one conclusion on basic principles in criminological problems is possible—that is, “your guess is as good as mine—until experience proves otherwise.” Some signs of haste should be removed—for example, the authors of the chapters are not given in the contents list; and we hope that any later edition will include an index, which should not be omitted from a practical handbook.

J. D. SUTHERLAND.

PRACTICAL ALLERGY

Office Immunology, including Allergy. A Guide for the Practitioner. Edited by Marion B. Sulzberger and R. L. Baer. (Pp. 420; illustrated. \$6.50 or 36s.) Chicago: The Year Book Publishers, Inc. London: H. K. Lewis and Co. 1947.

The qualification of this book's title is an understatement: discussion of allergy is not merely included but forms by far the greater part of the book. The authors begin with a full description of how to do tests for sensitivity, illustrating the text by photographs showing the technique of scratch- and patch-testing and of intradermal injection. The next section is about the immunology of infections, but, since the authors confine their account to what the practitioner can do in his own office, they ignore bacteriological and serological methods in diagnosis and mention only skin tests with antigens prepared from the micro-organism concerned. They even suggest their being used in diagnosing actinomycosis and filariasis, without any mention of examining the pus and blood respectively. The book would be more helpful if it included instructions for collecting specimens for the more usual laboratory investigations which give an unequivocal result.

The subjects of the remaining sections are Rh grouping, respiratory allergies, skin diseases (again largely allergic but oddly including actinomycosis and anthrax), spider, insect, and snake bites, and miscellaneous allergies. The authors fully describe methods of immunization and include lists of firms supplying the necessary materials. There is a prodigious list, running to 19 pages, of substances with which patch tests can be done, stating the vehicle and concentration to be used. Regarded as a practical textbook of allergy, this book presents to the reader a large and new if somewhat unreal world, and it may be found of much interest. When the authors discuss conditions not primarily allergic they give so incomplete an account as to be positively misleading to all but the well-informed.

L. P. GARROD.

GROWING OLD

The Years after Fifty. By Wingate M. Johnson, M.D. With a foreword by Morris Fishbein, M.D. (Pp. 153. \$2.00.) New York: McGraw-Hill Book Company, Inc.

This book is not to be regarded as an addition to geriatric knowledge. Although the author adequately surveys for the layman some elementary facts about disease, yet in a book on senescence it is a little disconcerting to find references to rheumatoid arthritis, prolapsed disk, and puerperal thrombophlebitis. The concluding chapters contain unexceptionable advice on the problems of ageing, but the author makes plain that the quality of our advice to those growing old has not improved upon that of Cicero, from whose *de Senectute* he quotes freely. It is also inevitable that

“Grow old along with me!
The best is yet to be,”

should be quoted, if only to convince the cynical that life would be difficult, and senescence intolerable, without self-deception. It is perhaps in the same vein that the author, who is Professor of Clinical Medicine in the Bowman Gray School of Medicine, of Wake Forest College, records the “apparently well-authenticated case of a North Carolina Confederate veteran who became the father of two children at ninety-four and ninety-six years of age.” However, robust American common sense cannot be altogether excluded, and we read with affection of Chauncey Depew, who lived to the age of 93, remarking that “the only exercise he took was acting as pallbearer for his friends who took exercise.”

D. V. HUBBLE.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

La Tuberculosis in Italia. By G. L'Ettore. (Pp. 284. No price.) Rome: Federazione Italiana per la Lotta Contro la Tuberculosis. 1947.

A general account with statistical tables of tuberculosis in Italy.

Modern Trends in Dermatology. Edited by R. M. B. MacKenna, M.A., M.D., F.R.C.P. (Pp. 432. 42s.) London: Butterworth. 1948.

Articles on various aspects of dermatology by different authorities.

Modern Methods of Amputation. By E. Vasconcelos. (Pp. 253. 61s. 6d.) Bognor Regis, Sussex: John Crowther. 1945.

Narcosis and Drug Addiction. By E. Hesse, M.D. (Pp. 219. 22s. 6d.) Bognor Regis, Sussex: John Crowther. 1946.

Discusses the ordinary drugs of addiction as well as tobacco, alcohol, tea, and coffee.

Introduction to Physiology. By W. H. Newton, D.Sc., M.D. (Pp. 284. 7s. 6d.) London: Edward Arnold. 1945.

Intended for the general reader as well as the medical student.

A Handbook on Hanging. By C. Duff. 3rd ed. (Pp. 79. 2s.) London: Freedom Press. 1948.

A light though informative account of the art of hanging.

Psychotherapy, its Uses and Limitations. By D. R. Allison, M.D., M.R.C.P., and R. G. Gordon, M.D., D.Sc., F.R.C.P. (Pp. 160. 8s. 6d.) London: Geoffrey Cumberlege. 1948.

A practical introduction for general practitioner and student.

Diabetes and the Diabetic in the Community. By M. E. Tangney, R.N. (Pp. 259. 14s.) Philadelphia and London: W. B. Saunders. 1947.

The management of diabetes described for the medical practitioner.

A Baby is Born. By G. M. Kerr, M.B., B.S. (Pp. 120. 3s. 6d.) London: Lantern Publishing Co. 1947.

A short book of advice for expectant mothers.

On Hospitals. By S. S. Goldwater, M.D. (Pp. 395. 59 or 45s.) New York: The Macmillan Company. 1947.

A general account of modern hospitals.

Microbial Antagonisms and Antibiotic Substances. By S. I. Waksman. 2nd ed. (Pp. 415. 54 or 22s.) London: Geoffrey Cumberlege. 1947.

The discoverer of streptomycin discusses the interrelationships of micro-organisms.

The Background of Therapeutics. By J. H. Burn, M.D., F.R.C.P. (Pp. 367. 22s. 6d.) London: Geoffrey Cumberlege. 1948.

A short account of the principles and practice of therapeutics.

Psychological Atlas. By D. Katz. (Pp. 142. 55s.) New York: Philosophical Library. 1948.

A varied gallery of illustrations to lectures on psychology, including composite photographs of faces, children's drawings, and paintings by the insane.

Bodies and Souls. By M. van der Meersch. (Pp. 463. 15s.) London: The Pilot Press. 1948.

A novel of medical practice in France; translated from the French.

Endotracheal Anaesthesia. By N. A. Gillespie, D.M., B.C.M.A., M.D., D.A. 2nd ed. (Pp. 237. 54s.) U.S.A.: University of Wisconsin Press. 1948.

A general account, including practical details and references.

Paravertebral Block. By F. Mandl, M.D., F.I.C.S. (Pp. 32s.) London: William Heinemann. 1947.

A monograph on the relief of pain associated with the autonomic nervous system.

Dermatologic Therapy in General Practice. By M. B. Sulzberger, M.D., and J. Wolf, M.D. 3rd ed. (Pp. 663. 57.75 or 42s. 6d.) London: H. K. Lewis. 1948.

A manual of modern methods in dermatology.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY MARCH 27 1948

THE REPRESENTATIVE MEETING

The Special Representative Meeting last week passed as a resolution the recommendation put before it by the Council of the B.M.A. This resolution urged that changes should be made in the National Health Service Acts of 1946 and 1947, and expressed the hope that by making such changes the Government would make it possible for the profession to co-operate. If the Government rejects this proposal and refuses to make changes in an Act which is unacceptable as it stands to 80% of the medical profession, then doctors will exercise the right given to them not to enter the Service. To make collective opinion effective the Representative Body (the R.B.) resolved that an Independence Fund should be established. This fund will be administered by trustees appointed for the purpose who will act independently of the B.M.A. The R.B. was in a decisive mood and inclined even to think that the Council's recommendation was not worded in strong enough terms. It would, indeed, have been easy for the Council to put before the R.B. a provocative recommendation which would have made impossible any new approach to the present difficult situation, already made more difficult and more unpleasant by the activities of trade unions and local Labour Party organizations referred to in the next leading article.

The two outstanding contributions to the day's proceedings were made by Lord Horder and Dr. H. Guy Dain, Chairman of Council. Lord Horder said that the B.M.A. now had the confidence of the profession in a fuller measure than ever before. This was not due to its mere numerical strength but to the realization that the B.M.A.'s policy "has crystallized in respect of those principles to give way on which would be to sell the profession's birth-right." "We believe," Lord Horder continued, "that the Association regards the points still at issue as we regard them, not bargaining points but signs of the doctor being a free man, free to practise his science and art in his patient's best interest." By sticking together we should win, but we could lose by squabbling about which of our principles is the most important. "We must not yield," Lord Horder said, "on any of the points which, collectively and individually, spell the doctor's freedom."

Dr. Dain, in a forthright speech, said it must be apparent to the whole country that there was something seriously wrong with an Act which provoked so strong a feeling against it as the plebiscite figures revealed. He discussed the situation as it had unfolded since January of last year, and observed that it was unfortunate that a problem of great national importance should have been approached either with emotion or in a spirit of party politics. "We want," Dr. Dain said, "to have regard only to the efficiency of the proposed service and to exclude it entirely from

political ideologies." The overall objection to the Act was against the powers of the Minister. "The Minister's power in this Act is absolute." If we entered this service without proper safeguards we should become servants of the Ministry of Health, whether whole-time salaried or not, and if this Act was not amended before it came into force we should have lost our independence and freedom. Dr. Dain emphasized once more that the people had been promised a free-for-all service available to everybody, and were going to be greatly disappointed. A wise Government, he considered, would have thought it proper to start such a service by stages. Among his concluding remarks Dr. Dain said:

Our position to-day is that we are willing to explore the problems afresh, provided that the outcome is a service in which the medical profession remains an independent profession, secure from domination by the State. We doctors want a health service. We want our services to be available to all who need them. We are ready to enter into any discussions directed to making it possible for the medical profession to co-operate with the Government. If the Government can show us other ways, new ways, of preserving our independence we are willing to listen. But if this cannot be done we owe it to the public to make our stand.

These last words of the Chairman of Council must be carefully considered by the medical profession and will, we hope, receive equal consideration by the Minister of Health. Speaking at a moment when the plebiscite has given the B.M.A. 40,000 votes of confidence in its policy, the Chairman of Council has opened the door to new discussions. It is now for the Government to respond to this gesture and to underwrite Mr. Bevan's assertion that he seeks the harmonious and enthusiastic co-operation of the medical profession. Like Lord Horder, Dr. Dain avoided discussing any particular point on which a settlement might be reached, and when the Cardiff Division moved that ownership of goodwill by practitioners, the abolition of basic salary and the powers of direction, and the right of appeal to the Courts be regarded as essentials in any settlement with the Minister, the R.B., after some discussion on this, accepted Dr. Dain's suggestion that they should pass to the next business. The R.B. gave no support to the Lothians Division in its plea for compromise, or for the view of its spokesman, Dr. G. W. Ireland, that "if you offer concessions and the Government remains adamant, public opinion will swing right round in your favour." In a subsequent discussion on the question of a new approach Dr. Dain repeated his observation that "we are reasonable people, ready to consider any possibility for securing a service consonant with the independence of Medicine." The R.B. rejected a motion in favour of an approach to the Prime Minister with a view to reopening negotiations, and supported the motion by the City of Edinburgh "that inasmuch as the medical profession believe that a complete health service cannot be made available to everyone in July, 1948, because of lack of staff and other facilities, this meeting is of opinion that particular consideration should be given in future negotiations to the possibility of introducing the Service by stages, as this becomes feasible."

Perhaps one of the most significant motions accepted by the R.B. was that put forward by Plymouth, "that in the

opinion of this Meeting the Act must be amended to guarantee freedom of expression to doctors in all matters relating to the clinical and administrative aspects of the National Health Service in which they are engaged." In whatever kind of a service the medical profession enters there will be no freedom or independence if the right to express opinion on all medical and professional matters is in any way restricted. In an article in *The Times* of March 15 this was one of the points which a special correspondent considered should be included in an amending Bill. The writer observed that an amending Bill was needed to remove from the Health Act the legal ambiguity affecting partnerships, and suggested that the same Bill might incorporate the four pledges recently given by Mr. Bevan and his colleagues: "They have assured doctors," *The Times* correspondent states, "that the new service will respect their freedom of speech and writing; that it will not impose a 'closed shop' on them or other health workers; that the executive councils (responsible for the general practitioner service) will choose their own chairmen when the initial Minister-appointed chairmen retire in 1949; and that local authorities will be pressed to co-opt local doctors and other experts on to their health committees." *The Times* correspondent suggests that these are "not 'concessions' except to common sense."

One representative observed towards the end of the afternoon that little had been said about the consultants' position in relation to the Act. The representatives had, on the whole, been more concerned with matters affecting general practitioners. It has been said that the consultants voted in the plebiscite in the way they did because of the desire to support the general practitioner. This was obviously one motive. But during the last three months it seems that the consultants have become more aware than before of the effect of the present Act upon themselves and their work, and upon the profession of medicine. The Royal College of Physicians and the Royal College of Surgeons have so far expressed no views. But the Royal College of Physicians of Edinburgh has passed a number of resolutions which it has submitted to the Prime Minister and made public on March 26. In the view of this College the result of the plebiscite can be explained only by the fear that the freedom of the profession is gravely endangered, and that this fear centres round the power of the Minister to alter by Order or Regulation the fundamental terms of service of the medical profession. The College goes on to urge that in the national interest negotiations should be resumed and that the matters in dispute should be re-examined and adjusted so that the medical profession may co-operate with confidence in the development of the comprehensive service desired by all. This is the first statement to be made by a corporation representing consultants, by the teachers of Medicine. It underlines Dr. Dain's observation about the powers of the Minister, and re-emphasizes the readiness of the profession to consider reasonable proposals.

This is not the time for face-saving devices or for the exhibition of pride that brooks no opposition. The Government, we suggest, should call a halt to the manoeuvres,

described in the next article, designed to browbeat the medical profession, and in the interests of the public as well as of the medical profession should respond to the moves made by the Chairman of Council and the Royal College of Physicians of Edinburgh.

PROPAGANDA

The Government, continuing to ignore the overwhelming opposition to the National Health Service Act on the part of those who will work under it, are proceeding to waste the country's money in an attempt to secure co-operation by compulsion. By the use of films, posters, and pamphlets they are preparing a huge publicity campaign to induce the public to bring pressure upon the medical profession. The trade unions, the Government's masters, are aiding and abetting this campaign. Some, at least, are using the strength of the organized workers as a means of influencing the decision of men and women who prefer to organize themselves on a voluntary basis.

During the Representative Meeting last Wednesday Dr. J. A. Brown, of Birmingham, moved as a matter of urgency the following resolution:

That this Meeting condemns as grossly improper the bringing to bear of pressure for political purposes upon individual doctors to induce them to inform outside bodies of their intentions in relation to the new service.

He then read three letters sent to individual doctors by two trade unions and a branch of the Labour Party. The Secretary of the Letchworth Trades Council wrote to a practitioner in that area saying that "the representatives of the twenty-two trade unions who attended would be grateful if you would very kindly let us know your intentions." The Letchworth Trades Council was acting on its decision to try to discover the number of medical practitioners who intended entering the Service on July 5. The day before this doctors in Rogerstone, Monmouthshire, received a more abruptly worded letter from the local branch of the National Union of Railwaymen. The secretary of this branch said he had been instructed "to inquire as to your views regarding the National Health Service Act to be operated from July 5," and went on to say that the members of his branch "wish to know if you are prepared to operate it on and from July 5." We may note that the Letchworth and Rogerstone letters were sent out within a day of each other, and it is perhaps not being too deeply suspicious if we see in this the guidance of a central band. Within three days of the issue of the letters referred to, a doctor in Cambridgeshire received one from the Histon and Impington Labour Party signed by the chairman and secretary of this organization, and also by the chairman and secretary of the Transport and General Workers' Union. He was asked whether he proposed to participate in the new service, and the letter ended thus: "Should your decision be a negative one we think it only fair that we should know this in order that we should be in a position to take such steps as may be open to us for the protection of our members." Dr. J. A. Brown pointed

out that no official invitation had been issued to any doctor to join the Service and that at the present moment the regulations of the Service had not been published; nor had the legal committee been set up to report upon the ambiguities of Section 35 of the Act. The branches of the three trade unions and Labour Party are doing Mr. Aneurin Bevan's work for him on the plea that they are anxious that their members will receive medical advice and assistance. They know full well that medical men will not use the trade union's weapon of the strike; and so far as we know no medical organization, not even the Socialist Medical Association, has circularized coal-miners and dockers with letters expressing anxiety about the effect on patients of a shortage of coal or foodstuffs in the event of a workers' strike. Whatever alarm we may feel about the effect upon health of a hold-up of essential goods and services, we like to believe that other groups of workers in the State are the best judges of their own conditions of work. There is only one answer which any medical man can give to these scarcely veiled threats, and that is that he will continue as always to give medical advice and care to those who seek it, but that he will not inform trade unions or local political parties of his intention to serve or not to serve under the National Health Service Act. Any doctor receiving such letters should forward them to the Secretary of the B.M.A., who will advise him what to do. These organizations are not instruments set up under the Act, and have no right to attempt to usurp the functions of the Local Executive Councils.

The dates of the letters referred to were March 10, 12, and 13. On March 15 the Ministry of Health issued a circular to local authorities on "Publicity Regarding the Services Available to the Public." "The most important aim of central publicity," the circular states, "will be to stimulate general interest in the new service." It is urged that local health authorities should take the initiative in publicizing details of the Service under the Act and in making arrangements to deal with personal inquiries. It is suggested that in some areas joint inquiry bureaux should be set up and that another method of dissemination of information should be through local voluntary societies.

There are already in the post offices of the country copies of a leaflet prepared by the Central Office of Information for the Ministry of Health, and it is believed that this and other publicity material will be released by the Ministry of Health about the middle of April. The burden of this leaflet is conveyed in the slogan, "Choose your doctor now." "If one doctor cannot accept you," the leaflet states, "ask another, or ask to be put in touch with one by the new 'Executive Council' which has been set up in your area." Of interest to insurance practitioners is the following statement: "If you are already on a doctor's list under the old National Health Insurance Scheme, and if you do not want to change your doctor, *do nothing*. Your name will stay on his list under the new Scheme." The leaflet urges the public to "act at once," to fill in application forms for each member of the family and to hand them to the doctor. The medical man has the right to time to make up his mind whether to join the new service, especially as the legal ambiguity about partnership

agreements is still unresolved. No one has the right to press him to a decision before July 5 and until he is in full possession of the facts.

This is the Minister's reply to the plebiscite. Does he really consider that the way to secure the co-operation of the medical profession is to couple the financial threat of loss of compensation with a propaganda attempt to persuade the community to coerce 40,000 doctors to enter the Service against their better judgment? The situation is getting beyond the bounds of common sense and human decency. We do not believe that the public wish to be treated by doctors bullied and threatened into a service they do not like, and we do not believe that medical men and women will allow themselves to be so coerced.

HEALTH IN WARSHIPS

The need for fresh air below decks in men-o'-war was recognized at least two hundred years ago, and at that time various attempts were made to improve the living conditions of the sailors who manned them. In 1734 Dr. Desaguliers exhibited to the Royal Society a model of a ventilating machine which could extract air from a room or impel fresh air into it, and a little later he used this appliance, which he called a centrifugal wheel, to ventilate the House of Commons. Not long afterwards troops were embarked at Spithead to proceed on an expedition against Spain, and the ill-health of these troops forced upon the Government the need to adopt some means of airing ships. Dr. Desaguliers was invited by the Lords of the Admiralty to exhibit his model; some of their Lordships saw the ventilator in the House of Commons at work, and the inventor was ordered to make a similar appliance to be tried in a warship at Woolwich. The trials were successful, but none of their Lordships witnessed them, and the Surveyor to the Navy, a prejudiced man conservative in his ideas, made an adverse report. Other schemes met with a rather better reception. After a long tussle a Mr. Sutton managed to get permission to ventilate a man-o'-war by drawing the air supply for the galley fire through the various compartments, and Dr. Stephen Hales secured a trial for his bellows-like ventilator. Yet the centrifugal fans on which the Royal Navy now relies for the ventilation of its ships are the direct descendants of the rejected Desaguliers machine.

One hundred years after these events, in 1844, D. B. Reid¹ wrote that the ventilation of ships had not at that time been placed on the systematic footing which was necessary to ensure comfort and success, but that of late it had been much improved in the Navy, with good effect on the health of the sailors. Reid referred to the great congestion which was common in ships of war and to the value of space, and he advocated the use of plenum ventilation in ships sailing to "localities dangerous from the state of the atmosphere."

¹ *Illustrations of the Theory and Practice of Ventilation*, 1844. London.

² "The Habitability of Naval Ships under Wartime Conditions." *Trans. Inst. Nav. Archit.* 1945, 87, 50.

³ Thorndike, E. L., McCall, W. A., and Chapman, J. C., *Ventilation in Relation to Mental Work*, 1916. New York.

Since those days the picture has changed. The Admiralty has endeavoured to ensure that ships are effectively ventilated and that a reasonable standard of accommodation is maintained. Neither of these results is easy to achieve. Space, as Reid noted, is very precious, and lavish allowances are impracticable. Yet if the initial space allowance is only just satisfactory any encroachment on it, or any increase in the ship's complement, will reduce the space per man to below the acceptable minimum. During the recent war such reductions in space occurred. Additional fighting equipment was introduced at the expense of living accommodation, and more men were needed to operate that equipment. In modern times efficient fans driven by electric power can supply large volumes of fresh air, but the ventilation problem is greatly complicated, especially in tropical waters, by the presence within the ship of much heat-producing machinery and equipment. Sims² has described some of the difficult problems which arose during the war in naval vessels.

In the years between the wars many investigations were made by the Industrial Health Research Board in this country, and by others overseas, of the effects of heat and of moderate cold on the efficiency and general well-being of the industrial worker. When the temperature was uncomfortably high or low sickness increased, and so did the accident rate. At high temperatures working efficiency declined, and in cold surroundings work which demanded a considerable degree of manual dexterity was done less efficiently. It is common experience that high temperatures are not conducive to efficient mental effort, but whether the reduction in efficiency is due to a diminished ability to work or merely to an increased disinclination for it has remained an open question. Psychologists in the U.S.A. studied the problem 30 years ago,³ but with inconclusive results. Probably their experimental conditions did not include sufficiently high temperatures.

Before the outbreak of war in 1939 much evidence showed the deleterious effects of high temperatures, and when during the war it became evident that there would be large naval concentrations in the Tropics the Medical Research Council's Royal Naval Personnel Research Committee was asked to study the environmental conditions in warships in the Tropics and to report on their probable effects on fighting efficiency. Attention was later invited to more general problems. Several investigations were undertaken in response to these requests. A comprehensive survey of the thermal environment and general living conditions in surface ships of the Eastern Fleet was made, and similar observations were recorded in submarines during Arctic and tropical cruises. Sickness reports were obtained from the Eastern Fleet and later from the British Pacific Fleet, and the data thus obtained were submitted to statistical analysis. Laboratory experiments on the effects of heat on efficiency in both physical and mental tasks were undertaken, and a study was made of the efficiency with which work was done in ships. These investigations, and the results obtained, are described in this issue by Surgeon Commander F. P. Ellis, the Naval Secretary of the Royal Naval Personnel Research Committee, who himself carried out some of the work.

The Admiralty provisionally accepts an effective temperature of 80° F. (26.7° C.) as the upper desirable limit of warmth in living and working spaces in ships, and

86° F. (30° C.) as the upper acceptable limit. Ellis points out that in the ships of the Eastern Fleet the average effective temperature observed in each of the types of compartments listed was above the upper desirable limit, and in many of the main working spaces the upper acceptable limit was exceeded. In some of these spaces there was much radiant heat, and in these the effective temperatures corrected for radiation were substantially above 86° F. Living conditions were congested. Of the 8,000 men living in a number of ships of the Eastern Fleet the majority had less than 19 sq. ft. (1.76 m.²) of floor space on the mess decks, and in the Tropics many of the men found their hammocks too hot and slept in the open air on the upper deck.

Observations in submarines showed the importance of adequate hull insulation, both in the Arctic and in the Tropics. With good insulation satisfactory temperatures can be maintained when the submarine is submerged, but on the surface the effects of climate are felt to a greater extent. Discussing accommodation in submarines Ellis remarks that the best use is made of the space available, with the result that a surprising degree of comfort is obtained. An investigation of the bacterial content of the air in a submarine showed that even when the vessel was submerged the concentration of bacteria-carrying particles rarely exceeded 50 per cu. ft.—a result attributed to the adherence of the particles to oily bulkheads and machinery.

The sickness returns covered an exposure of about 450,000 man-months. Sickness was much more prevalent in ships than in shore establishments, mainly because of the greater incidence of skin diseases and minor accidents. Prickly heat was almost universal in many ships. The great diminution in cases of minor sickness during cruises out of the Tropics to South Africa and Australia left no doubt about the importance of hot, humid atmospheres in causing ill-health. During the first twelve months after the defeat of Japan the average amount of sickness was about twice as much in ships stationed in the Tropics as in those of the Home Fleet, while for ships in the Mediterranean the figure was between the two.

Physiological studies confirmed the American finding that men could perform heavy physical tasks for short periods without collapsing when the degree of warmth was greater than that generally encountered in the Eastern Fleet. In another study the efficiency of wireless operators was found to fall off between effective temperatures of 83° and 87.5° F. (28.3° and 30.8° C.)—temperatures which were commonly met with in the Eastern Fleet. This result is noteworthy, for it gives experimental proof that efficiency in mental tasks is adversely affected by excessive temperatures.

In a concluding note Ellis remarks that we have reached a stage where satisfactory design can proceed only if precise and accurate data on human requirements and limitations are available, and he mentions the ways in which the required particulars are now being obtained. Nowadays there is much talk about humanizing industry, and from Ellis's account it is clear that the Admiralty is not only very much alive to the importance of the human factor in maintaining the traditional efficiency of the Royal Navy but that it is actively promoting research into human problems.

THE INDEPENDENCE FUND

The Special Representative Meeting last week approved the recommendation of the Council that an Independence Fund should be established, and the first Meeting of the Trustees of the Fund was held on Thursday, March 18. The Fund is an independent entity and is not part of the organization of the B.M.A. The Trustees have issued an appeal for money and have decided not to invite a renewal of the guarantees made to the previous Guarantee Fund. The two main objects of the Independence Fund are to provide financial aid to practitioners who may suffer hardship in the event of a continuation beyond July 5 of the present conflict between the medical profession and the Government; and to provide through Local Independence Committees throughout the country an organization for maintaining the unity of the profession in its expressed determination not to accept service under the National Health Service Acts of 1946 and 1947 until such amendments have been made as will preserve the freedom of the profession. The National Insurance Defence Trust has deposited with the Fund an initial contribution of £400,000. The Trustees are appealing to individual doctors to give what they can to make this Fund effective for the purpose. They suggest that there are few practitioners in established practice who cannot afford to give £100 as a first contribution. In a statement just issued the Trustees state: "The danger to the independence of our profession is a measure of the need for generous giving. . . . We appeal to you to give all you can afford in order to conserve the freedom which neither we nor the public can afford to lose." The Trustees are twenty-three in number, and have appointed Dr. H. Guy Dain as Chairman, Lord Horder as Deputy Chairman, and Dr. G. F. Buchan as Treasurer. The other Trustees are: Mr. A. Lawrence Abel, Dr. J. C. Arthur, Dr. J. A. Brown, Dr. R. W. Cockshut, Dr. W. E. Dornan, Dr. A. Staveley Gough, Dr. I. D. Grant, Dr. F. Gray, Dr. E. A. Gregg, Dr. Charles Hill, Dr. W. M. Knox, Dr. J. B. Miller, Dr. J. C. Pearce, Dr. J. A. Pridham, Dr. W. D. Steel, Prof. G. I. Strachan, Dr. S. Wand, Sir Reginald Watson-Jones, Dr. D. J. B. Wilson, and Dr. W. Woolley.

POLIOMYELITIS

In July last year we drew attention to the unusual prevalence of poliomyelitis.¹ A few weeks later it was clear that something like an "American experience" of the disease was to be expected, and we published in successive issues papers by Dr. W. H. Kelleher² and by Prof. H. J. Seddon³ and discussed the general problem of its management.⁴ There followed at a later stage some discussion of the terminology of poliomyelitis and polio-encephalitis.⁵ The Kenny method⁶ was reassessed and interest revived in the still unsolved problems of distribution and spread. Towards the end of the epidemic McAlpine and his co-workers⁷ revived some of the clinical lessons that had been learnt, and Ritchie Russell⁸ made an important contribution relating physical activity in the pre-paralytic stage to the severity of paralysis.

These clinical studies preceded the epidemiological surveys which were set in train in October.⁹ One of these surveys has now been completed, and its results are reviewed by Bradley and Gale¹⁰ in a paper which was published this week. From the point of view of the Registrar-General there were 53 weeks in 1947 and 9,262 "original" notifications of poliomyelitis and polio-encephalitis in

England and Wales. Corrected notifications will probably total 7,600 or less, giving an attack rate of 3.8 per 100,000 population for the largest epidemic known in this country. Bradley and Gale analyse the replies to a questionnaire addressed by the Ministry of Health to hospitals throughout England and Wales. The 270 replies received cover the period from Jan. 1 to Oct. 11, 1947, and relate to 6,762 patients admitted with a tentative diagnosis of poliomyelitis or polio-encephalitis. The diagnosis was confirmed for 4,717 patients, of whom 2,687, or 57%, were males. The inquiry includes therefore about three-quarters of all the cases occurring in England and Wales.

There was no difference in the age distribution for males and females, and for both sexes combined 30% of the patients were under 5 years of age, 35.1% were aged 5-15 years, and 34.9% were aged 15 and over. The case mortality increased with age from a minimum of 3.2% at ages 1-4 to 34.7% in those aged 45 and over. The case mortality for males was slightly higher than that for females; for all ages the rates were 8.2 and 6.9%, respectively.

Of the 4,717 confirmed cases 2,976, or 63%, had paralysis chiefly affecting the limbs and trunk, and in 485, or 10.3%, the paralysis affected chiefly the cranial nerves. There were 333 deaths among these 3,461 paralysed patients, and of the 3,128 who recovered 1,285 (41.1%) were classed as "mild," 1,205 (38.5%) as of "moderate" severity, and 638 (20.4%) as "severe." Altogether 188 males and 122 females had to be treated in respirators; 217 were so treated temporarily and 93 are likely to need such treatment permanently. Related to the whole epidemic these figures suggest that lengthy hospital treatment will have to be provided for about 3,000 patients, one-third of them under 5 years of age, one-third at ages 5-15, and one-third of 15 or over. The preponderance of males over females in this group will be about 5 to 4, and it is probable that about 1,000 of these patients will be severely crippled.

There was no paralysis in 1,256 of the 4,717 confirmed cases. Changes in the cerebrospinal fluid made diagnosis possible in 769 of these patients; 328 were diagnosed on clinical grounds; and in 159 of the patients the symptom and signs were indefinite, but the diagnosis was made because of close contact with a proved case. The diagnosis was confirmed in 760 women of child-bearing age, and of these patients 71 (9.3%) were pregnant. The proportion of pregnant women among the general population of women of child-bearing age during 1947 was 9.4%. In this epidemic, therefore, there was not an unduly high incidence of the disease in pregnant women. The trend of the epidemic generally was in accord with those already reported for other countries of Western civilization.

MEDICAL MEN ELECTED F.R.S.

The following members of the medical profession were elected Fellows of the Royal Society on March 18: Robert Alexander McCance, Ph.D., M.D., F.R.C.P., Professor of Experimental Medicine in the University of Cambridge, for his contributions to metabolic studies of human beings; Sir Leonard Gregory Parsons, M.D., F.R.C.P., F.R.C.O.G., Emeritus Professor of Diseases of Children in the University of Birmingham, for his studies on child health and the wasting disorders of children; and William Albert Hugh Rushton, Ph.D., M.R.C.S., L.R.C.P., Lecturer in Physiology in the University of Cambridge, for his researches on the effect of electrical stimuli on muscles and nerves.

On Monday, March 22, Lord Moran was once again elected President of the Royal College of Physicians.

SIR FRANCIS CHAMPNEYS

CENTENARY OF BIRTH

The centenary of the birth of Sir Francis Henry Champneys, Bt., M.A., D.M., F.R.C.P., was celebrated on March 25 at St. Bartholomew's the Great, London. We print below an abridgment of a memoir prepared by his son, Sir Weldon Dalrymple-Champneys, Bt.

On March 25, 1848, there was born, in London, Francis Henry Champneys, who devoted his life to the sacred cause of motherhood and after many years of bitter fighting in the face of great opposition gave the country a fully trained and regulated midwifery profession, thus saving the lives of millions of British mothers and their children.

Francis was the fourth son of the Very Rev. William Weldon Champneys, D.D., afterwards Vicar of St. Pancras, Canon of St. Paul's Cathedral, and Dean of Lichfield (1868-75). Dean Champneys' grandfather had also been Vicar of St. Pancras and Sub-Dean of St. Paul's Cathedral. Dean Champneys was a profoundly religious man and a leading figure in the Evangelical revival. He was also a pioneer in several social movements for the care and education of the poor, starting one of the first "ragged schools" in England while in his second curacy at St. Ebbe's, Oxford, and continuing this work when he went to London. He also secured the passing of an Act in 1842 which gave the "coal-whippers" for the first time the right to establish offices of their own instead of having to tout their coal round the public houses.

Francis was thus brought up in a strongly religious atmosphere, but it was by no means a stifling one, for the deepest affection and understanding existed between the Dean, his wife, and their five sons and two daughters. Francis' love of music stands out as one of the first and most marked of his characteristics. In 1860 he won a scholarship at Winchester College, and there he continued his organ lessons under Samuel Sebastian Wesley, who was organist to both the college and the cathedral.

In 1866 he won an exhibition at Brasenose College, Oxford, where his father had been a scholar and fellow (1831-7). He read natural science at Oxford, studying under Prof. Rolleston,

and took a first-class in that school in the Michaelmas term of 1870. During one of his long vacations he stayed up at Oxford to dissect a chimpanzee, this work being the subject of his first medical publication, entitled, "On the Muscles and Nerves of the Chimpanzee and Anubis," which appeared in the *Journal of Anatomy and Physiology* for 1872. In 1871 he entered the medical school of St. Bartholomew's Hospital, and the following year he was elected a Radcliffe Travelling Fellow. During the half of his three years' tenure of this Fellowship, which had to be spent abroad, he worked at Vienna, Leipzig, and Dresden; at Dresden he held an appointment at the Royal Lying-in Hospital. On his return to England in 1875 he took the qualifications of M.R.C.S. and B.M. (Oxon).

and was immediately appointed medical registrar at St. Bartholomew's, and in 1876 he was admitted a Member of the Royal College of Physicians of London. In the same year he married Virginia Julian, only daughter of Sir John Warrender Dalrymple, 7th Baronet of Luchie, North Berwick, a descendant of the first Lord Stair and a first cousin of the Earl of Haddington.

The year after his marriage he was appointed casualty physician at St. Bartholomew's in addition to his other work, his brother casualty physician being his friend Robert Bridges, later Poet Laureate, with whom he maintained contact all his life, both of them dying in 1930. Robert Bridges once reckoned that he saw about 30,000 patients in the casualty department during the year, and was thus able to devote on the average one and a quarter minutes to each patient! In spite of this killing pace Champneys was able to keep very interesting notes of these casualty patients, some of which were contributed to the *St. Bartholomew's*

Sir Francis Henry Champneys, Bt.

Hospital Journal in 1943* by his son, Sir Weldon Dalrymple-Champneys.

Champneys had already been attracted towards obstetrics by the teaching of Matthews Duncan, then physician accoucheur to the hospital (1877-90), a rugged Scot of outstanding personality and very decided views. All his life Champneys spoke of his teacher with the warmest admiration and affection, and the teacher must have had great belief in his pupil, for he did his best to advance his career and showed him many kindnesses. In those days and indeed much later the hudding

**St. Bar's Hosp. J.*, 1943, 47, 223.

sultant was faced with a grim struggle whatever his ability, so Duncan's encouragement must have meant a great deal to him in his early years. It was characteristic of Champneys' innate modesty that even after his appointment in 1880 as assistant obstetric physician to St. George's Hospital he regularly attended Matthews Duncan's 9 a.m. lectures at St. Bartholomew's. At St. George's he was assistant to Robert Barnes, and when Barnes resigned in 1885 at the age of 68 Champneys succeeded him, but had to carry the whole weight of the department, as no assistant obstetric physician was appointed to the vacant post. In the same year as Champneys had been appointed to the assistant post at St. George's he had also been appointed, with Sir John Williams, who became one of his greatest friends, as obstetric physician to the General Lying-in Hospital, York Road, and his connexion with this hospital, of which he became president in succession to Lord Lister, lasted all his life. It was here, where devastating outbreaks of puerperal fever had recently been sweeping the wards, that Champneys and Williams made history by applying Lister's antiseptic principles for the first time in any English maternity wards and with the dramatic success which seems so natural to us now but was then so sensational. He was elected a Fellow of the Royal College of Physicians in 1882, a Councillor from 1902 to 1904, and served as an Examiner for the Conjoint Board from 1887 to 1891 and again from 1903 to 1907. He was offered, but declined, the honour of nomination as Harveian Orator.

From his student days he had been appalled by the way in which unskilled midwives and "handywomen" spread infection, illness, and death among the mothers and babies of the country, and he was determined to fight this evil with all the skill and energy at his disposal. This fight, which was not crowned with success until 1902, was the greatest work of his life. In 1876 he had become a Fellow of the Obstetrical Society of London, which in 1872 had set up a Board for the Examination of Midwives to conduct a voluntary examination of women proposing to practise as midwives and to grant where appropriate a certificate that the woman in question was "a skilled midwife, competent to attend natural labour." Up to this time there had been no control of women practising as midwives, the majority of whom were ignorant handywomen with dangerous and unhygienic methods. In 1890 Champneys was elected chairman of this Board. Though the setting up of the Board was a step in the right direction and the diploma was for many years the hall-mark of a well-trained midwife, this did not satisfy Champneys, and he fought hard for the next twelve years to achieve his ambition of making motherhood as safe as possible by establishing a compulsory training and qualification for all midwives, thus finally abolishing the unskilled "handywoman," the cause of so many maternal and infant deaths.

This proposal met with the bitterest opposition from inside and outside the medical profession, but Champneys drove fearlessly onward in his crusade that was to save the lives of millions of British mothers and their babies. Stirred up by agitators in the profession, the General Medical Council threatened the Obstetrical Society with anathema for infringing the Medical Act and deceiving the public, and even hinted at the word "infamous" being applied to the officials of the Society who signed the midwives' diplomas. The agitators claimed that they were "creating a new order of medical practitioners," to which Champneys replied (in his presidential address to the Society in 1895): "This is as correct as the classical definition of the crab which was criticized by Cuvier; it is perfectly accurate, except that (1) we have not 'created' any persons at all; (2) midwives are not 'medical practitioners' (in the technical sense); and (3) if either doctors or midwives are 'new,' I fear that history tells us with no uncertain voice that midwives antedated doctors by an enormous length of time. It is hardly too much to say that midwives must have begun nine months after there were two women and one man on the earth." He was attacked by many of the general practitioners for taking the bread out of their mouths and received threatening letters, but nothing was able to deter him from the great task he had set himself. He showed conclusively that "any person is at liberty by the law of the land to render aid to any other in time of sickness if desired; any person is at liberty by the law of the land to receive such aid

from any other; unskilled aid leads to lamentable consequences to poor mothers and children; midwives are a necessity." "The question," as he pointed out, "is not whether midwives shall exist, but whether they shall be as good or as bad as possible." The registration of midwives was, in fact, the best protection of medical men against the usurpation of their medical functions.

By close reasoning, fearless fighting, and scrupulous fairness Champneys gradually won the admiration and support of the profession and of the general public, till in 1901 he persuaded the Government to promote the Midwives Bill, which was passed the next year, following which he was entrusted with the extremely delicate and difficult task of conducting the affairs of the new Central Midwives Board, a task which he fulfilled with outstanding success for the next twenty-eight years, never missing a meeting until his last illness.

On Sept. 1, 1890, Matthews Duncan had died, and in the following January Champneys was invited by the Governors of St. Bartholomew's Hospital to succeed his old teacher as physician accoucheur to the hospital. The title of this post was a relic of the time when caesarean section represented practically the only cutting operation in obstetrics, and this tradition had survived the expansion of surgery resulting from the two great discoveries of anaesthesia and asepsis, so that abdominal surgery for gynaecological conditions was still carried out by a surgeon on the staff, in this case Harrison Cripps, and not by the physician accoucheur, though he was a skilful surgeon and operated frequently on his private patients. On Champneys' retirement both the scope and the name of the post were changed, but the former physician accoucheur was wont to comment with regret that the younger members of his specialty had become too surgically minded.

Champneys and Cripps were thus very closely associated for many years. His tenure of this post from 1891 to 1913 was a period of ever-increasing and more varied activity, during which he rose to undisputed pre-eminence in his branch of the profession and acquired a world-wide reputation.

The traditions of his profession were to him a precious heritage to be guarded at all costs, and this is well brought out by a passage in his presidential address to the Obstetrical Society, from which I have already quoted: "A patient is a person who requires a doctor; a doctor is not, in the same sense, a person who requires patients. A patient is not, primarily, an organism for extorting so many guineas or shillings per annum, as an aphid exudes syrup at the titillation of an ant, or a cow secretes milk under the blandishments of a dairymaid. This is a fact often forgotten."

In spite of his numerous preoccupations, music was never entirely neglected, as is shown by his composing during this time several tunes for his friend Stainer's "Hymns Ancient and Modern," writing a number of articles for the "Dictionary of Musical Terms" produced by Stainer and A. W. Barrett in 1876, and forming a private choir about 1878. He also employed his musical gifts to the benefit of his hospital, and Sir Norman Moore wrote of him, in his *History of St. Bartholomew's Hospital*, that "as a learned and admirable musician he benefited the school of St. Bartholomew's by encouraging the practice of music there." When on July 25, 1893, Winchester College celebrated the quincentenary of its opening a performance was given of the "Carmen Saeculare Wiccamicum," with words by G. H. Cremer and music for four voices with organ and pianoforte obbligatos composed by Champneys. He was a frequent visitor to the organ loft at St. Paul's Cathedral during the times that his friends Sir John Stainer and Sir George Martin presided there.

Reference has already been made to the events which led up to the passing of the Midwives Act of 1902, in some ways the crowning achievement of Champneys' life, but by no means the last important contribution which he made to the advance of his specialty and the welfare of the whole profession and nation. Of his work as chairman of the Central Midwives Board his successor, Dr. J. S. Fairbairn, wrote: "For 27 years he was annually re-elected by its members as chairman of the Board and, more than any other of its members, was responsible for moulding its procedure and policy. Its early problem was the difficult one of a new and untried body gaining the

confidence of the divergent interests represented by the practising midwives it controlled, the general practitioners that came to their aid, the medical officers of health who supervised their practice, and the teachers who had to follow the Board's instructions on training. That the new body succeeded in working smoothly and avoiding serious controversy, even so far as to secure general approval, was a remarkable tribute to the sagacity and tact of the man at the wheel. His was no nominal chairmanship, for he was always in touch with the business of the Board and word perfect in his part before each meeting; he was ready to sum up each item on its agenda and had a resolution in draft prepared for discussion."

In 1910, in the first honours list of his reign, King George V conferred upon him the honour of a baronetcy. In the same year that the Central Midwives Board came into being Sir William Japp Sinclair, of Manchester, with the support of Champneys, John Williams, and C. J. Cullingworth, founded the *Journal of Obstetrics and Gynaecology of the British Empire*. Champneys was a director of the journal company from the first, and in 1907 succeeded Sir John Williams as its chairman: and when, after its suspension in 1915 because of the war, it was revived as a monthly publication in 1921 he was again elected chairman and persuaded to retain that post in spite of his advancing years, because, in Dr. Russell Andrews's words, "we could not possibly find a more efficient or more trusted chairman." Sir Comyns Berkeley, who was editor of the revived journal, has recorded that, fearing he could not devote sufficient time to ensure its success, he wrote to Champneys, who at the end of a characteristic letter of encouragement remarked, "Medical men who are too busy to do anything, according to their own report (and still more of their wives), have generally little to do."

His long and distinguished connexion with the Royal Society of Medicine started with his membership of at least two of the Societies whose amalgamation in 1907 brought the R.S.M. into being. As has been already mentioned, he had been since 1876 a Fellow of the Obstetrical Society of London, but he had also been a prominent Fellow of the Royal Medical and Chirurgical Society of London and a frequent contributor to its *Transactions*. He was therefore eminently fitted to play an important part in the task of amalgamating thirteen separate societies representing the different branches of medicine and surgery. His international standing in his subject was shown by his election as president of the Section of Obstetrics and Gynaecology at the 17th International Congress of Medicine held in London in August, 1913. Another activity which was to take up a great deal of his time and energy was the General Medical Council, to which he was appointed as a Crown nominee in 1911, and of which he remained a member until 1925. When in 1911 the National Insurance Bill was under heated discussion Champneys was the chairman of a sub-committee of the Council which formulated their comments on the proposals in regard to maternity benefit. Sir Norman Walker has written of his activities on the Council that "he was a very valuable committee man, and his opinions were much valued and respected."

A good description of him at "Bart's" in his prime was given by the late J. D. Barris, who was one of his favourite interns and later succeeded Champneys on the honorary staff. "Those of us," he writes, "at St. Bartholomew's Hospital who trained and served under him have vivid recollection of his striking presence. We felt in him the man of character and of high ethical and moral standards, so that later he became our example and guide in all that concerned the management of our patients and our professional conduct. He spoke to us with the voice of authority, and we listened to him with admiration and respect. He was so clear, incisive, prompt, and businesslike. His punctuality was proverbial; we knew when two o'clock would strike (for that was the appointed hour of his afternoon round in Martha Ward), that at this hour precisely he would sweep across the square in his open landau, for this was before the days when motors had ousted the more graceful carriage and pair. Arrived at the foot of the seventh block, a short, virile handsome man would alight and as often as not would scorn the lift in order to go to the third floor by the stairs, taken at the run all the way, his intern and students panting after him, unless we had had the fore-

sight and time to forgather in Martha Ward beforehand. Later still it was the privilege of some of us to know him as the adviser and friend to whom we could always turn. He was without doubt a great public servant who advanced the interests of his subject and shed lustre on his hospital."

During the 1914-18 war he not only continued to conduct the affairs of the Central Midwives Board but in addition he travelled about 20,000 miles lecturing to the troops on venereal disease on behalf of the National Society for Combating Venereal Disease, now the British Social Hygiene Council. After the war, at the request of his old friend Sir Clifford Allbutt, he undertook the chairmanship of the Examiners of Midwifery at Cambridge, though he was then over 70 years of age. He greatly enjoyed the companionship of Allbutt, with whom he always stayed on these occasions. In 1922 his wife died, and at the end of the funeral service at St. Alban's, Holborn, he walked across to the organ and played some of her favourite music, saying it was the last little bit he could do for her except prayer.

One of the last contributions which he made to the advancement of his specialty was to use all his influence, experience, and tact in helping the foundation of the British (now the Royal) College of Obstetricians and Gynaecologists, and in recognition of these services the College paid him the highest compliment in their power by electing him a Vice-Patron. Dr. Russell Andrews has recorded that in a conversation with him only six days before his death he showed a lively interest in the College and in the proceedings of the latest Council Meeting, which he had been unable to attend on account of illness. So on July 30, 1930, Sir Francis Champneys, then in the 83rd year of his age, passed away peacefully at the Sussex home he had loved so well, having given the mothers of his country a fully qualified midwifery profession in place of a body of ignorant and dangerous handymen and having raised the status of obstetricians and gynaecologists by a lifetime of devoted and unremitting labour, always giving God the praise.

Grateful acknowledgment is made to the Editor and Proprietors of the *Journal of Obstetrics and Gynaecology of the British Empire* for permission to quote freely from their "In Memoriam," published in 1930, Vol. 37, No. 3.

MR. BEVAN ADDRESSES ALMONERS

The Minister of Health, Mr. Aneurin Bevan, addressed the annual meeting of the Institute of Almoners on March 12. Prof. Alan Moncrieff presiding. Mr. Bevan said that the duties of the first hospital almoner, appointed to the Royal Free Hospital in 1895, were to prevent abuse of the hospital by persons able to pay for medical treatment, to refer persons already in receipt of private relief to Poor Law authorities, and to recommend suitable persons to join provident dispensaries—a rather meagre programme which went only a very short way indeed to revive the generous profession of almoner in the mediaeval monastery. The first hospital almoners were little more than means-test agents, concerned much more with the financial help of the hospital than with the mental and physical help of the patient. Much progress had been made since then; the concept of "social medicine"—an awkward phrase—had arisen, and it was now understood that the work of the doctor failed of its full effect unless reinforced by such work as the almoner could carry out in connexion with the social background of the patient.

Under the new Health Service, Mr. Bevan continued, it would no longer be necessary for the almoner to concern herself with the financial position of the hospital; her concern would be solely with the patient. The anxiety of large sections of the population—and those not the poorest—concerning doctors' bills and hospital payments would disappear. This was one of the most important revolutions which had ever taken place in the treatment of the sick. The almoner would represent the patient to the hospital management committee; she would see that proper facilities for his accommodation were provided—waiting-rooms, canteens, all that sort of thing—and she would link up hospital services with general-practitioner and local-authority services on the one hand and with resettlement and rehabilitation services on the other. Her duties would be

further enlarged later on when health centres were developed. It was one of the most regrettable features of our present materials shortage that it had not been possible to develop health centres as quickly as had been hoped. It was never expected that health centres would spring up by July 5. The more ambitious programme would have to wait until more resources were available, but wherever it was possible to adapt an old building or to use a new building a start on health centres would be made.

The Health Service not a Bureaucracy

After speaking of the value of the almoner's work in cases of incipient mental illness, Mr. Bevan went on to say that consultation among those working the new Health Service would take place to a greater extent than it had ever done before.

"We do not want the Health Service of the future to be a bureaucracy. That is the very last thing we want. We want health workers in every field to be organized and represented on the various bodies, so that policy from time to time may be shaped and directed by the workers themselves in the various health fields. For the first time this will be possible, and of course for me or any Minister of Health this is essential. The National Health Service Act is not like some other pieces of legislation. The Minister of Health is responsible to Parliament for the whole health system. The responsibility of the Minister of the Crown to Parliament is the medium by which all health services will be brought to public accountability. . . . After July 5 the Minister of Health will be the whipping-boy for the Health Service in Parliament. Every time a maid kicks over a bucket of slops in a ward an agonized wail will go through Whitehall. After the new Service is introduced there will be a cacophony of complaints. The newspapers will be full of them. I am sure some doctors will make irate speeches. The order paper of the House of Commons will be filled with questions, and for a while it will appear that everything is going wrong.

"As a matter of fact everything will be going right, because people will be able effectively to complain. They complain now, but nobody heeds them. What the Health Act will do after July 5 is to put a public megaphone in the mouth of every complainant so that he will be heard all over the country. As the months go on and the limelight of publicity is brought to bear upon every aspect of the Health Service, for a while it will be almost intolerable. But this public scrutiny will have a medicinal effect. Everybody will be on his toes. Everybody will know that his actions are liable to be matter for public debate. The Minister in the House will be a shock-absorber between Parliament on one side and the vast body of health workers on the other. This period of interrogation is an essential prerequisite for the organization of the Service. You almoners will be able on many occasions to provide an emollient, and to the extent you do your work properly and intelligently my own work will be eased.

"The Health Service," said Mr. Bevan in conclusion, "is being launched in stormy waters, but then the launching of any big ship causes considerable water displacement. It was hopeless to expect such a service to be started without controversy. But it will be a very great revolution. It is being watched by every country in the world. There will come over here a stream of visitors to find out how it works and how its difficulties are being resolved. We shall of course find from time to time that alterations and adjustments have to be made. We are not ridden by doctrine; we are a nation very largely of visionary empiricists, able to adjust things where necessary, and between us we shall have a standard of health service that will be the envy and admiration of the world."

In reply to a vote of thanks Mr. Bevan further said that the polemics surrounding the Service would soon disappear and be settled. Whatever might be their quarrels or their policies, these were relatively quite unimportant when the work they had to do was considered.

Sir Ernest Rock Carling, a member of the Executive Committee, who introduced the annual report, said that 790 candidates had been interviewed during the year for the post-war emergency courses of the Institute. The first hundred to qualify in these shortened courses had had little difficulty in securing posts of all types. During the year 203 certificates altogether had been granted, about half to candidates who had qualified after the shortened course and half after the normal course. The number of members on the register was just over 1,000. The wastage rate due to matrimony was very high. Sir Ernest pleaded that the training of the almoner, at present supported on the fees of students alone, should be subsidized by the Government.

THE COMMONWEALTH FUND

One of the examples of selective philanthropy for which the United States is noted is the Commonwealth Fund, which last year appropriated 1,614,000 dollars for programmes and special grants in the field of medical education and research and public health and mental health services. The Commonwealth Fund was founded twenty-nine years ago, at first as a service for delinquent and problem children. One of its first achievements was an institute for child guidance in New York, where teachers for child-guidance clinics might be trained. Its second project was a child health service which was set up in a number of States. From this it moved to the betterment of American health by means of the rural hospital, assisting communities where hospital facilities were difficult of access. The Fund then widened its activities to support research and teaching in medical schools. In a retrospect of its work it observes:

Medical education is basic to nearly everything that the Fund is trying to accomplish. It is the only sure road to comprehensive medicine. It underlies public health work. It is a daily objective of the well-conducted hospital. It is inseparable from medical research. . . . But medical education is in ferment; ideas long in germinating are beginning to bud furiously like yeast. The Fund shares with medical educators everywhere a deep concern that physicians shall be taught, and shall have opportunity to teach themselves, how to practise the best contemporary medicine.

Finally, thanks to the warm friendliness of its founder, the late Edward S. Harkness, towards the British people, the Fund established a number of fellowships for British students. From 1925 until their suspension during the war these fellowships had entitled over 400 students, technicians, and Civil Servants in Great Britain and other parts of the British Commonwealth to spend some time—usually two years—in the United States with ample opportunity for the studies they wished to follow and for extensive travel. The fellowships have now been resumed, and in 1947 the normal quota of twenty were awarded by the British committee, under the chairmanship of Sir Walter Moberly, to students at British universities, not all of them for medical studies, but some for studies in political science, economics, international law, and such subjects. The six fellowships for medical studies were at Harvard, Columbia, and St. Louis, and the subjects endocrinology, forensic medicine, cardiovascular surgery, psychiatry, and haematology.

In the twenty-ninth annual report of the Fund an account is given of its stewardship during the past year. It has continued to assist medical education in many of the American universities, has made grants for the development of public health services in six States, and has subsidized various mental health projects, including two in Great Britain. Thirty-four investigations on medical subjects at twenty American universities or other scientific institutions have received some support from the Fund during the year, and as a result of these subsidized projects twelve works and about 135 medical and scientific papers have been published.

"The analysis of the genetic basis of emotional behaviour thus remains a field for the future. On its investigation may well depend the acquisition of knowledge of fundamental importance to human education and behaviour. We have neglected such study because of a quixotic and erroneous belief that studying the emotional behaviour or misbehaviour of even young human beings was taboo. The blind and impractical worship of euphonious but sterile dicta of unscientific leaders, who have mistaken 'declarations' of human equality for truth, have too long held us spellbound. All around us are tragic evidences of the evil that uncontrolled or prostituted emotion can create. Our own place in the family of nations has been perilously risked and is still insecure because of this factor which is still abroad in the world. Even the basis of our own emotional control and integrity within the bounds of our national and personal problems is still largely a jungle of ignorance. Expensive social, economic, and educational systems present impressive exteriors but are unsound at the core, because the human beings of which they are made remain largely well-dressed, housebroken savages whose behaviour remains creditable only so long as the strain on it is not too great. There is no reason why emotions cannot be studied and trained as well as intellects, so that the risk of their exploitation and disintegration can be decreased, to the greater security and happiness of all."—"Parental Influence," by C. C. Little, in *Genetics, Medicine, and Man* (Cornell University Press, 1947).

Correspondence

Signs-manual of Freedom

SIR,—I am sorry that my article in *The Sunday Times* (not my letter to *The Times*) horrified Dr. John V. Mainprize (March 13, p. 519). My reason for picking out remuneration by capitation fee and right of appeal against dismissal was that I was dealing with the acceptance of those two principles by the Northern Ireland Act. Though it is true that, as a consultant, the retention of goodwill does not affect me directly, I have tried to make it clear that *all* the signs-manual of a doctor's freedom—and this is one of them—are of vital interest to every one of us.—I am, etc.,

London, W.1.

HORDER.

Ownership of Goodwill

SIR,—At a recent B.M.A. meeting many doctors expressed a desire to yield to the Minister of Health on any points not absolutely essential to the preservation of our freedom. In this connexion the question of the purchase and sale of practices was discussed. I think that the distinction, in this case, is not merely between the abolition of the purchase and sale of practices on the one hand and the preservation of this custom on the other, but rather between a centrally administered and monopolistic control of the appointment of doctors to all spheres of medical practice on the one hand and some more democratic arrangement on the other.

It has been argued that a doctor selling his practice is actuated in his choice of his successor by considerations other than the suitability of the purchasing doctor to conduct the practice. This may be true, but we have Willesden to remind us that considerations other than medical proficiency may influence public bodies responsible for making medical appointments. In this connexion it would be well for members of all political parties to remember that, whatever they may think of the present Minister of Health, the Minister of the future may belong to the extreme "left" or the extreme "right" politically, and there is no doubt that the administrative structure of the new Act would offer a magnificent opportunity to a Communist, should such a one, by that name or any other, one day assume the office of Minister. A man loses his freedom when he loses his right to change his employer should he object to the terms of his service, the character of the service he is instructed to give, or to any other conditions, political or otherwise, imposed upon him.

It has been said that a doctor selling his practice does not necessarily concern himself with the professional ability of the incoming doctor, but against this I would argue that the purchasing doctor has to assume responsibility for his own ability. He has to decide whether he considers himself competent to conduct a general practice or not, and he knows that the patients will pass judgment upon this important matter in the near future. He will not lightly make a wrong decision knowing that if he does so the goodwill of his practice, for which he has paid, will dwindle away. It is a matter between the doctor himself and his patients, whose servant he is, and I believe that he and they are the people best able to judge his competence.

The problem of to-day is the failure of faith in man the responsible individual and the deification of the State "as the universal provider and the authority determining all thinking and willing" (see quotation from C. G. Jung's *Essays on Contemporary Events* in Dr. Ahrensfeldt's interesting letter—March 13, p. 516). The question men have to decide is whether they will maintain their faith in the man on the spot, aware of conditions and of the results of his decisions and actions, or the man remote in the fastness of Whitehall. Where faith rests, there responsibility and power should rest also. It is for the patients themselves to decide whether they would prefer to have their doctor appointed for them by the State or whether they would prefer to exercise some responsibility in this matter through the democratic power of valuable goodwill, a power vested ultimately in their own hands.

The goodwill of practices is worth a very large sum of money. Money is power. When one speaks of the power of money people are apt to think of a few rich people exercising undue

power over others. They forget that as the wealth of a country becomes more evenly distributed among its members so the power of money becomes increasingly a democratic one. So it is with the power derived from the value of goodwill. This power is vested ultimately in the hands of the patients themselves. Is it wise to take this power away from the many and centralize it? Is it wise to do this at any time, and particularly now, when the threat to our freedom and to the whole structure of democracy is like the hot breath of some devouring animal upon us?—I am etc.,

Reading.

BETTY F. HILL.

SIR,—I am in entire agreement with the views of Drs. Ida M. Will, J. H. Francis, and R. A. Furniss (March 13, p. 519). Provided they are satisfied that the Northern Ireland Act does not conflict with our "Principles," the B.M.A. Council should state clearly, emphatically, and with every method of publicity available: "The Northern Ireland Parliament has passed a Health Act similar to the one in this country but without its objectionable features. If such an Act were adopted in this country, with only one modification, we should be prepared to advise our members to accept service under it immediately." Such a statement would be well within the understanding of even the meanest intelligence among the general public.

Modification: ownership of goodwill. The Minister is taking away from us something that has stood the test of time without replacing it by a satisfactory alternative. Few of us like squatting, few of us obtained our present goodwill by squatting, and fewer still of us who have spent long years in insalubrious areas care for the thought that, in order to obtain a change of scene in later life, we shall have to go through the process of squatting (always an undignified posture even on physiological occasions) without even the capital from our previous goodwill on which to live during the lean years. Convertible Government bonds in lieu of the present never-never system of compensation would help to alleviate this. For the young man embarking on practice for the first time the only alternative would be a real encouragement to enter partnership with an existing practitioner; how this could be made to function equitably without some element of purchase of goodwill in the partnership either by cash or by extra work I cannot fathom.

May I suggest, Sir, a reprint of your leading article of Sept. 20, 1947? We do not all, I regret to admit, file away our old *B.M.J.s.*—I am, etc.,

Edlington, Nr. Doncaster.

R. S. GILCHRIST.

Dr. Taylor and the Health Service

SIR,—In your leading article (March 6, p. 454) you criticize some of the points in Dr. Stephen Taylor's letter published in the same issue (p. 463). You will no doubt receive many letters from other readers about that same letter, which, however, raises so many controversial issues that I feel that an extra letter may not be superfluous.

Dr. Taylor in his opening sentence says he is "a Labour Member of Parliament who happens also to be a doctor" and thus sets the standard of his whole letter. "The Labour Party has accepted the Act," "our Labour Party," and many other such pointers are sprinkled through it. Here, surely, naked, unashamed, and nauseating is the epitome of partisan approach which has done so much to make this Act anathema to so many doctors. Here speaks the arrogance of a political party at present in the majority, with the lack of respect for the opinions of others, however fitted the latter may be to advise on a highly specialized subject, which has already been made notorious by Mr. Shinwell and the "tinker's cuss." Dr. Taylor makes great play with the fact that the other political parties support the Government over many points in the Act, and Mr. Bevan in the House of Commons tried to make capital of the fact that the B.M.A. had not seen eye to eye with previous Ministers of Health any more than with him. What better proof is there that the B.M.A. is not a party political organization? Surely through the fog of political squabbling emerges the fact, clear to all but those who do not wish to see, that the medical profession opposes this Act for the same reason that it has opposed the others—because it is a bad Act. When a Government of this country introduces a good Bill (and such a Bill could easily be produced by consultation between experts in the Government

and experts in the profession) then I am sure that Government, whatever its political colour, will have the fullest support of the medical profession and the B.M.A.

Dr. Taylor says he is concerned primarily with the needs of his constituents for more doctors. Why then is he so wholeheartedly in favour of an Act which will spend millions of pounds (many of which will come from his constituents) and give them neither hospital beds, health centres, nor more doctors for many years? Since he "happens also to be a doctor," the implication is plain!

Dr. Taylor also points out that any Government in the future can alter decisions arrived at now, a point frequently stressed by the B.M.A. But he does not seem to draw the moral that seems obvious—namely, that we should therefore keep our heads out of the noose. He says we all want to avoid bureaucracy. So we do, so why support an Act which is going to saddle us with yet another army of bureaucrats at a time when our man-power is said to be short? Surely we have enough already.

Dr. Taylor asks every doctor to think over carefully the issues at stake. To my mind, and I believe to the minds of many other younger members of the profession, the fundamental issue is quite clear. It is freedom which is at stake, and that is always worth defending. The points at issue are the outward and visible signs, but their significance goes much deeper. If the B.M.A. were to yield in these points, even though plausible people would have us believe they are unimportant, then the freedom of the medical profession in this country might well be lost for good; and as we have seen in the last ten years, medicine is a flower that does not flourish in captivity.

Dr. Taylor finishes his letter with some words of advice to the profession. It seems to me that because some people have voted for him and returned him to Parliament that does not qualify Dr. Taylor to proffer advice to a highly educated and trained body of men who, perhaps more than any other body of men in the country, are able to think for themselves. However good the intention, I am sure many will agree with me when I say that I consider it impertinence and conceit of a really amazing degree.—I am, etc.,

London, S.W.3.

H. E. LOCKHART-MUMMERY.

Profession's Independence

SIR,—The foundations of the new Health Service (the health centres, the hospital extensions, and the increased facilities for training medical students) are not in sight, let alone under construction. The attempt to bring in the full Service on July 5 next is to risk everything without bringing benefit to anyone. The effect on the schools of the Education Act, in spite of the emergency training courses for teachers, is a lesson to us, and on these grounds alone the operation of the Act should be postponed.

But Dr. F. M. R. Walshe's letter (Feb. 28, p. 407) is timely. It becomes increasingly clear that the real issues before us are moral and ethical, and we must not be distracted by practical details which are by comparison of little importance. Attention should be fixed on the persistently inadequate presentation, and frequently misrepresentation, of the doctors' case in Parliament and certain sections of the Press, notably *The Times*. The views of the minority who approve of the Act in its present form are less important than the belief that all who oppose them are activated solely by a "determination to sabotage the Labour Government" or motives of monetary gain. Clinical or ethical issues requiring a sober and reasoned analysis are clouded by political prejudice or a materialist philosophy of life that precludes the holders from conceiving, let alone understanding, any other viewpoint.

Dr. Stephen Taylor (March 6, p. 463) is probably right when he contends that any safeguards for the doctors' freedom secured by amendments to the Act would be of little or no value, as Parliament could modify such provisions at any time. It is therefore essential that no steps should be taken that could in any way weaken the profession's independence. With the lights once again going out in Europe this is no time for the doctor to give up the control of his means of production, together with his freedom of speech, thought, and action. If we as doctors fail to give a moral lead at this point we shall lose the trust and respect of our patients, and deserve to do so.—I am, etc.,

London, W.1.

ALAN MABERLY.

Deprivation of Initiative

SIR,—Dr. G. C. Pether (Feb. 28, p. 411) calls attention to the psychological effects of the Minister of Health's proposed medical service and invites opinions. I would agree with him that there would be likely to be unhappy psychological repercussions were doctors to try to work under the conditions proposed in the new Act as it stands at present. Dr. Pether states that there would be "cramping and thwarting of the personality inherent in the massive schemes of the planners."

Regimentation, interference, and exploitation would be rife—all factors that conduce to a neurosis in the Serviceman in wartime. Nietzsche divides men into slaves (or the masses) and the higher man. By this latter he implies one who is happy in his capability to indulge in original thinking and to this extent to take risks, as opposed to the majority who, putting safety first, need security and are willing to entrust their welfare to some authority that will work to this end. Such are unhappy if they even think individually. Doctors should not be encouraged to put themselves into this group. Where authority denies to any minority group of men permission and opportunity to develop freely and expand (in their own time and way)—should they wish to do so—the end result can only be to build up inwardly protests and hate towards such a frustrating authority. This is bound to slow up activity and so prejudice efficiency.

Negative affects can only be dealt with in one of two ways. (1) Either they lead to the adoption of an unhealthy submissiveness (or slave reaction), brought about by the enforced blinding of the critical faculties—good for neither masters nor slaves—or (2) they lead to an apparently peaceful acceptance by the group with a liability to periodic violent outbursts, most harmful to the satisfactory evolution of a planned and progressive service such as we would all wish to see. Dr. F. M. R. Walshe in his excellent letter (p. 407) entitled "The Common-place Mind" reinforces this point of view. He quotes from *The Revolt of the Masses*, by Ortega y Gasset, who asserts that "the mass crushes beneath it everything that is different, everything that is excellent, qualified, and select." It will be a sad day for the world when democracy becomes identified with the mass that crushes out original thinking and with it all that psychological treatment aims at encouraging. It is only a comparatively small number of men that can think objectively without emotional bias creeping in and distorting perspective. They should be encouraged, not discouraged.

In your annotation (p. 399) you refer to the importance the educated men attach to the freedom to criticize the administration of the service in which they serve. Were this not to be permitted it would be a bad thing for the service itself—as occurs in the R.N. and R.A.M.C. The medical profession because of its training, which is essentially concerned with basic and physiological facts of life, is best qualified to think objectively. To do efficient work doctors must not be regimented as a profession. As Dr. Pether puts it, they should be left free to develop as fully adult individuals. In other words the job of the medical man, whether a psychologist or not, is to help his patients to become adult so that they may think ahead and do their own planning. This will be the more difficult for doctors to do if they are to be themselves forced into a service in which they are deprived of all initiative and all powers of criticism of the administration.—I am, etc.,

London, W.1.

CYRIL WILSON.

Doctors who Might

SIR,—Most of your correspondents appear to agree that the retention of the ownership of goodwill is of paramount importance, and there can be no doubt that if we lose it we shall be in a very poor position to negotiate with the Government if it should choose to introduce new and unwelcome measure at some future date.

Lieut.-Col. James T. Harold (March 13, p. 518) refers to ex-Service doctors, etc., who might be induced to undertake service under the Health Act owing to economic pressure, but such people should consider matters very carefully before taking such a step, however difficult their present financial circumstances. It is obvious that a salary of £300 p.a. implemented by a few transfers from established practitioners at 15s. 2d. per head will not be sufficient for them to subsist on, whereas,

with the retention of goodwill, purchase price could be borrowed on life insurance at a gross cost of 12% p.a. spread over 10 years (about 9% after income tax rebates have been deducted), and at the end of that time the capital (greatly increased if we have inflation) would be realizable if the doctor should wish to move elsewhere.

Let the would-be entrant to general practice realize that we, the established practitioners, are fighting his battle as well as our own for freedom in our professional life. If we stand out, as I for one intend to do, against the financial pressure which is being brought to bear against us, the opportunist will have the option of entering the Service and gaining a practice at the expense of those of us who are adhering to our principles. To put it briefly, if we, the established practitioners, were to accept the Act, the new entrant would have to "put up his plate" at £300 a year, but if we refuse he would be in a position to reap a rich harvest. Let anyone considering the latter course examine his conscience and decide whether it will allow him to gain a living at the expense of those who are striving to maintain the rights and freedom of the profession for generations to come.—I am, etc.,

Kirkby-in-Ashfield, Notts.

J. D. DURANCE.

The Independence Fund

SIR.—Is it of any use to reiterate our reasons for refusing to accept service unless we also counter the economic threat which the Act presents? It surely is this which makes the Minister feel that he only has to sit back and say nothing. He is well aware that a large number of doctors have such liabilities that, when they know that certain neighbours already have decided to join and that others are in the same dilemma as themselves, they may be overwhelmed by the fear of bankruptcy. The obvious remedy is to raise such a sum of money by subscription and guarantee that these members may feel completely independent. If we have sufficient conviction we certainly can do this.

The sum I would suggest is of the order of £20,000,000, or an average of £500—the price of a car—from each of the 40,000 doctors who voted "No" in the plebiscite. Many, of course, can guarantee very much more than this, just as many cannot afford nearly so much; but for all it will be a question of the price at which they value their liberty. Twenty million pounds will allow £3,000 to each of 5,000 doctors, with £5,000,000 to give temporary assistance to specialists and consultants.

The first effect of the scheme will be to show the Council how many are prepared to stand firm. The second, if this is really "our finest hour," will be to show how strongly and sincerely our convictions really are; and because of this I believe that Mr. Bevan, who, after all, is staking his political future, would meet us in a very different spirit, and that we might hope to have such amendments that all who wished could join happily and cheerfully.—I am, etc.,

Beckenham, Kent.

W. MAXWELL PENNY.

The Doctor's Oath

SIR.—In some of your leading articles and in many of the letters which have recently appeared in the *Journal* there has been a recurring and an increasingly insistent stress laid on the question of the doctor's conscience in relation to taking service under the Act. Most of the writers rightly draw attention to the fact that the doctor's primary duty is to his patient and not to the State, and that this centuries-old tradition of primary service to the patient will be greatly endangered or completely nullified by the intervention of a State paymaster. In the terrifying spread of State power which we are witnessing in the world to-day it was never more true to say of all men, and particularly of doctors, that no man can serve two masters.

Many doctors, if not most, feel themselves vaguely bound by the ethical precepts outlined in the Hippocratic Oath. Unfortunately, however, neither the original oath nor its later Christian modification is now taken by doctors, either before or after graduation. In a recent letter to a lay journal Dr. Tudor Jones has expressed the opinion that if the oath, particularly its Christian form, had been taken and kept by every doctor the introduction of the present Act would have

been impossible. In outlining how the original meaning of the Oath has, of set purpose, been steadily whittled away, he goes on to state: "It is a truism of politics that power does not vanish; it can only be transferred. The history of the Medical Oath is the history of the transference of power from the individual to the 'State.' It is a long history. The effect of the transference is the reign of the immoral law in place of the Moral Law."

While vigorously opposing the introduction of this Act by all practical means, many doctors are realizing that we have been betrayed into a false position by this continued undermining of the moral basis of our profession. Most of us have been rather late in recognizing this process, so the movement to reverse it should begin now. Might I suggest that the administration of the Christian form of the Medical Oath be revived, that doctors already qualified should be given the opportunity of taking it, and that we press on the medical faculties and the Royal Colleges the desirability of reintroducing the Oath as an integral part of the graduation ceremony?

I can well understand the mind of those who would consider my suggestion to be a long-term solution for a short-term problem, but I would point out that the fifth of July is not the Last Day. Neither, unfortunately, is it the First Day. The profession has lost one defensive position after another through the habit of dealing with the symptoms of a social and moral disease as they happened to appear. It is now time to deal with the disease itself, its cause, and the only sound method of cure.

I would be grateful if any doctors interested in the practical realization of the above project would write to me at the address below.—I am, etc.,

17, Monkham Avenue,
Woodford Green, Essex.

L. P. GRAY.

Petition against the Act

SIR.—Continually we are told that Parliament represents the "will of the people." Is this so? I worked during 1946 in a very large panel practice in an industrial area in the Midlands, where I spoke with many patients about the Health Act, and not a single one wanted their doctor to be a State-controlled doctor but a free man. Since then, working in this very rural practice I have found only two patients who appeared (rather half-heartedly, though) to approve of the Act, or, rather, to side with the Government against the doctors.

The Government will be convinced that this Act is against the wishes of the people only if it is shown definite proof that this is so. In order to obtain this proof I suggest that the B.M.A. organizes immediately a petition to be sent to the Prime Minister. If the public are circularized with a clear statement of the doctors' objections there will be at least a 75% majority of the population who will vote against the Act. If paper shortage renders circularization impossible then I suggest that in each district public meetings are arranged by doctors (all the doctors of that district appearing together on the platforms) and the public made aware of our point of view and an opportunity be given to sign the petition. The petition could also be signed in our waiting-rooms.—I am, etc.,

Wool, Dorset.

THOMAS B. L. BRYAN.

Building without Bricks

SIR.—July 5 is not far distant, and I think it is now necessary to drop, once and for all, discussion concerning "doctor-patient relationship," freedom, moral issues, and a hundred other etceteras. What I want to know is, How can we give a better health service if we have no more hospital beds, no more staff for the hospital, no new clinics, and no new equipment etc.? Will the patients be better served after July 5? I do not think so unless we have at our disposal the means to give them better service. We require better tools and we will finish the job, but the mere introduction of a scheme does not make matters one bit better for a patient who cannot get treatment. It is perfectly clear that the introduction of the scheme is premature, as we have not at our disposal the means to carry it out.

Once again, turning to the practitioner who is going to earn his living by working a satisfactory scheme, I want to warn him that payment by capitation fee—i.e., 15s. 2d. to 18s.—

is going to spell financial failure, more especially, if he is a rural practitioner with a small panel who derives the major part of his income from private patients. You may have private patients after July 5, but not for very long. I will close by asking one more question: Is a practitioner's experience in years of practice of no financial value?—I am, etc.,

Callander.

F. C. M. McILWRICK.

A Compromise

SIR,—May I suggest a compromise which might retain our essential freedoms while allowing the Government to meet our demands? (1) Basic salary to be paid to doctors in under-doctored areas only; all doctors to be free to enter public practice anywhere on capitation fees only. (2) The General Medical Council and the new Tribunal to be merged into a new body, an improved G.M.C., which will keep the *Register* as at present. (3) Compensation for goodwill to be paid at the earliest possible date, and sale of house or surgery to be unrestricted; a doctor should be free to sell his own property for what he can get for it, and when health centres are provided there will be no need for an income to buy a surgery. (4) When a doctor retires from the area all his patients should be asked to choose again.

Point 1 above removes the need for direction, helps those who want help, and allows a doctor who so wishes to semi-retire to a quiet area. Point 2 avoids the appeal to the Courts issue. If a doctor is unfit for the public service he is unfit to be on the *Register*, and vice versa. Point 3 would satisfy some of the critics of buying and selling and would encourage doctors to enter existing practices as partners or assistants, chosen by those they are to work with, of course, rather than squat and hope for the best. Point 4 would remove the illusion that patients are bought and sold. I hope that these suggestions will not be dismissed as weak, for I think that we have here the desired freedoms so far as is possible in a 100% service. Our present unyielding attitude can only wreck the whole scheme if persisted in. May I say that I propose to stick to the majority if it remains large enough, but I do feel we could make the next move towards a settlement.—I am, etc.,

Paignton.

J. F. BURDON.

Postpone Until Workable

SIR,—After attending the meeting of the Scottish Representatives on March 10 I left with a feeling of complete insecurity. Practitioners of my age who have been working on their own for about thirty years are asked to accept conditions under an Act of which they disapprove and also to be in complete dependence upon an income fixed by the computation of their share of a certain sum derived from taxation of the population. I cannot understand why the medical profession should be subject to a bond which no business man or body of men would accept for a moment. In these times of fluctuation of the value of money it would be perfectly ridiculous if there were no clause in the Act whereby our emoluments were not adjustable to the variation of the cost of living and increased taxation.

I consider that the Act is, under present conditions, absolutely unworkable and also dishonest. The public is asked (rather *made*) to contribute to a national fund administered by the Socialist Government without being told that the present situation of medical arrangements is becoming gradually more desperate, and that to improve it many years of hard spade work will be necessary. In order to live decently doctors are having gradually to increase their private fees—at least, I am doing it gradually, because no one likes very sudden things. Nursing associations and hospitals are crying for more nurses. Plenty of plans for this and that are being made, but from whence comes the all-important trained specialist staff?

We find all our industry crippled by the exportation of vital transport and other necessities which we badly need ourselves for recovery. Taxation has gone so far as to be increasingly imposed upon necessary medicine. This reduces the chemist and dispensing doctor to the position of unpaid tax-collectors and falsifies their books, while at the same time increasing the cost of treatment. While we all realize the benefit of inoculation, maternity subsidies, and special allowances for the sick, it must be remembered that all these public services demand filling up of *forms* and making out of *claims*. The unfortunate

person who requires a "certificate" cannot help it, but it must be remembered that we doctors have no option either in the matter, have never been asked whether we will or will not do all this extra work, and do not receive any pay for doing it. Yes, we are sick and tired of forms and certificates, and now we are in danger of being all our lives under the necessity of reporting everything we do, and depending for our living upon every person "choosing" us bringing another "form."

Sir, I hope that the British Medical Association will advise the Government to postpone the foundation of a National Health Service *until it can be worked*, and until every member of the public can realize that he or she will derive increased benefits from the proposed taxation involved. In the meantime, I am sure, we shall all work to improve conditions, and expect help from the Government in so doing.—I am, etc.,

Coldingham, Berwickshire.

F. O. TAYLOR.

Parliament Defying the Public?

SIR,—The Minister's suggestion that we are defying Parliament has greatly damaged our cause with the public. Could it not be made clear to them that the boot is really on the other leg? (1) Parliament, realizing that a service manned by reluctant, resentful, and recalcitrant doctors must be inefficient, has decreed that each individual doctor shall choose freely whether he will or will not enter the Service. (2) Four months before the appointed day the Minister was informed that a great majority of the profession, in exercise of this legal right, would choose to stay out. (3) The Government can now ask Parliament to amend the Act so as to make participation (a) compulsory or (b) acceptable. (4) If they do neither it would seem that they hope to stultify the freedom of choice, conferred by Parliament, by fear of financial consequences.

It seems odd that trade unionists should wish to coerce a profession by means which they would be the first to denounce if applied to an industry. Perhaps they do not realize that, since we cannot use the "strike weapon," any doctor entering the Service under the present Act will be absolutely committed to docile acceptance of whatever conditions of service the present or future Ministers may choose to impose. The choice before Mr. Bevan now is between providing an efficient service for the public and trying to score a personal victory for himself at the public expense.—I am, etc.,

Paignton.

ATHELSTANE HILL.

Contracting Out for Patients

SIR,—As one of many "lay" people who have long been fighting the imposition of a centralized health service, I am glad to see that doctors are realizing that, far from having given a "mandate" for it, the public has never been consulted or told the facts. This comes out in a good many letters recently published in your columns, and Dr. W. H. Spoor (Feb. 28, p. 412) renews the question, "Has the patient's right to contract out from the Service been dropped, and, if so, why?" while Mr. Reginald T. Payne (March 13, p. 514) faces the fact that "the interests of the public and the interests of the profession both call for the repeal or abandonment of this Act."

The question of "opting out" for patients has been raised many times in the B.M.A., and, with all due respect to a profession which is doing more than any other to defend the freedom of everyone, it cannot be "dropped" without a betrayal of the patients' interests. It is the essential corollary of the doctor's right to retain the ownership and goodwill of his practice; the one without the other is, in the long run, untenable. Freedom of choice in a matter so closely affecting the private life is a fundamental human right, to deny which is to declare for despotism.

As for the nonsense about doctors "buying and selling patients" when a practice changes hands, it is a good example of the notorious political trick of accusing one's opponents of one's own intentions. Any doctor who accepts "compensation" in connexion with the surrender of patients against their will to the control of the politicians, is "selling" them, and the Government is "buying" them, because they will have had no choice in the matter. When a practice is sold normally, the patients have a perfectly free choice, of course, and can contract out of the new arrangement. Freedom of choice is of the

essence of the whole business, and if the doctors will not concede it to patients, as to themselves, they are isolated and lost.

In conclusion I would add that I write not for myself alone, but for over seven thousand people who have signed a demand for the right to contract out, and a declaration that they will work for the repeal of any legislation which infringes it—I am, etc.,

Bangor, N. Wales.

C. G. DOBBS.

"What do the Doctors Want?"

SIR.—When Hitler was building up for his aggressive war upon the liberties of the world, a part of his technique was to declare himself an essentially reasonable man whose generous intentions were consistently misrepresented by gangs of ruffians, Jews, capitalists, reactionary "old men," and other miscreants. His "patience had been exhausted" in the struggle to instil his reasonableness into an irrational world. "What," he would then demand rhetorically, "do the English—or the Democracies—really want?"

Mr. Bevan has borrowed extensively from this technique, and he and many of his supporters in the House repeatedly ask the same kind of question in the same kind of rhetorical way. What they are trying to do, of course, is to shirk the obvious duty of the plaintiff to prove his case and to throw upon the defendant the onus of proving his innocence. If you want to change the world, it is up to you to show reason why it should be changed; there is no reciprocal obligation upon the world to prove that it does not need changing.

But this significant point is apt to be missed, and Mr. Bevan's rhetoric has had a considerable measure of success both with the Press and the public. At public meetings recently one hears the question asked again and again, What does the B.M.A. want? or What do the doctors want? These questions have a sufficient flavour of reasonableness to be echoed by a large part of the audience. They are posed, not only by the political agitators who haunt such meetings, but by the ordinary thoughtful citizen, whose papers have led him to believe that the doctors are being reactionary and obstinately obstructive to a fine forward movement.

Such questions are difficult to answer from the platform of a public meeting. The Act as it stands is so monstrous that it can easily be torn to pieces; but when that is accomplished the citizen, looking half-consciously to the doctors for a constructive lead, asks not unreasonably what we can put in its stead. I think the real answer is that the doctors, with their immense tradition of public service, know that sweeping revolutionary reforms are usually bad, and that it is best for the world that the art and practice of medicine should be suffered to evolve gradually, stage by stage, under the guidance of those who have given their lives to it and with the minimum of interference from the political State.

Hamstrung as we are by every kind of shortage, there is only one major reform that can usefully be introduced at the present time—the reform repeatedly pressed by the B.M.A. upon successive Governments—that the benefits of National Health Insurance be extended to the dependants of panel patients. That is a crying need. No other revolutionary change should be contemplated until the national finances have been put in order and until the shortages of doctors, nurses, hospital domestics, hospital beds and equipment, houses and health centres, food, and the general amenities of living have been remedied.—I am, etc.,

Orpington, Kent.

A. C. E. BREACH.

Decentralize Power

SIR.—In the letter "Criticism from Holland" (March 6, p. 465) we have in my opinion the most important argument against total State control of doctors. We have the history of Germany, with its total State control of medicine, sterilization of political opponents, etc. Certain services (a few only) could be carried out by the Government—e.g., irrigation schemes, electric power schemes—although even these could be carried out by co-operative effort in natural areas.

State control is clumsy and prevents refinement. Freedom is a necessity for a high standard. Countless laws, regulations, rules, forms, certificates, confuse the mind and spirit. The

"panel yoke" is a true description of panel service and I agree with the writer of the letter of March 6 (p. 469). Let us have more freedom for all. An alternative health service, an extended insurance service, a comprehensive scheme, etc., may be as total as the present one which we have rejected. We need to get away from totalitarianism by decentralization of power.—I am, etc.,

Liverpool.

S. PUGMIRE.

Plato on Free Doctors

SIR.—Plato is generally recognized as one of the greatest thinkers and writers of the world, and it is interesting to recall his comments on the National Health Service although they were written 2,300 years ago. The following passage is taken from *The Laws*: "Did you ever observe that there are two classes of patients in states, slaves and freemen; and the slave-doctors run about and cure the slaves, or wait for them in the dispensaries—practitioners of this sort never talk to their patients individually, or let them talk about their own individual complaints? The slave-doctor prescribes what mere experience suggests, as if he had exact knowledge; and when he has given his orders, like a despot, he rushes off with equal assurance to some other servant who is ill; and so he relieves the master of the house of the care of his invalid slaves. But the other doctor, who is a freeman, attends and practises upon freemen; and he carries his inquiries far back, and goes into the nature of the disorder; he talks with the patient and with his friends, and is at once getting information from the sick man and also instructing him as far as he is able, and he will not prescribe for him until he has first convinced him; at last, when he has brought the patient more and more under persuasive influences and set him on the road to health, he attempts to effect a cure."—I am, etc.,

London, W.8.

H. STEPHEN PASMORE.

Direction under N.H.S.

SIR.—I was glad to see Dr. R. L. Osmaston's letter (Feb. 14, p. 312). The misstatement that he refers to (it is in the leading article "Money and Freedom," Jan. 24, p. 153) is present also in "The Minister's Reply Examined" (Jan. 17, p. 109)—"a few cases of 'under-doctoring'"—and unfortunately this commentary was, I believe, circulated to all practitioners whether readers of the *Journal* or not. It would be good to see a public correction and to hear of an apology to Mr. Bevan. This would help maintain the honour of the B.M.A. and would also help to clear the air.—I am, etc.,

Kendal, Westmorland.

R. B. WILSON.

Mental Health of Students

SIR.—It is interesting that the only special investigation that Dr. John Pemberton (March 13, p. 490) undertook himself was to "assess the mental health" of the students. Presumably he subjected each student to a psychiatric investigation.

He purported to show that 20% of the students were suffering from "minor anxiety states or depression." Depression is a mood disorder which can occur in normal and many abnormal people and is not in itself a diagnosis. If "minor anxiety state" means anything it means psychoneurosis—mild anxiety state. Yet it is quite clear that Dr. Pemberton did not include his group of minor anxiety states under psychoneurosis, which he considered separately. Similarly he set up a separate category, hysteria, which he did not group under psychoneurosis. He did not indicate what he included under psychoneurosis: when he had abstracted anxiety states and hysteria from the group. Two conditions he named—"marked introversion" and "nervous breakdown"—are not accepted psychiatric syndromes.

From all this one is forced to the conclusion that Dr. Pemberton is either using the current psychiatric diagnostic terminology incorrectly or is setting up a new jargon of his own. If the latter is true then he should state clearly and in detail what he means by the terms he uses. If, for instance, "marked introversion" means shy, normal personality and "minor anxiety state" means worried, normal personality, Dr. Pemberton should state so in plain English.

Finally, Sir, it would be interesting to know exactly what investigations Dr. Pemberton did undertake. Did he subject

his students to psychometric tests, personality tests, such as the Rorschach, and questionnaires designed to show abnormal traits, or did he just rely on his psychiatric intuition?—I am, etc.,

Sheffield.

F. J. KELLEHER.

The Problem of Chilblains

SIR,—I am grateful to Dr. William P. McKeever (March 6, p. 475) for drawing attention to a terminological error in my paper (Feb. 21, p. 336). As a result of experiments on the effect of cold on cellular metabolism it was found that cyanosis did not develop in a hand that was immersed in cold water for as long as six minutes when the venous return was stopped by a tourniquet, but rapidly developed on transferring the hand to hot water. The failure to develop cyanosis in the first place was no doubt due to impaired cellular activity, and the development of cyanosis in the second place was due, most probably, to the accumulation of the waste products of cellular metabolism and the consequent increase of reduced haemoglobin.

When the hand was returned to the cold water, with the tourniquet still in position, the cyanosis slowly disappeared and at the end of six minutes had been replaced by a bright red colour. I suggested that the reason for this must have been a dissociation of the carbon-dioxide-haemoglobin relationship (I used the term carboxyhaemoglobin in error).

I am aware that it is stated that cyanosis only appears when 40% of a normal haemoglobin content exists as reduced haemoglobin (Price's *Textbook of the Practice of Medicine*, 1942 p. 339), but on this basis I found it difficult to explain the disappearance of the cyanosis on exposure to cold. It is hard to imagine why cold should decrease the percentage of reduced haemoglobin present, assuming the venous circulation to be stagnant in the area under consideration. That cyanosis may develop from other causes is evident from the fact that sulphonamide medication may cause it; in this case the cyanosis may be due to either methaemoglobin or sulphaemoglobin (*ibid.*, p. 16).

In my paper I tried to avoid being dogmatic regarding the nature of the products of cellular metabolism which cause the inflammatory reaction found in chilblains. I prefer to leave the elucidation of this point to colleagues who have a greater knowledge of biochemistry than I possess.—I am, etc.,

Ilkley, Yorks.

R. JOHN GOURLAY.

The Design of Bed-pans

SIR,—Although the practice of getting patients out of bed soon after operation will to some extent solve the problem of that nerve-shattering act the use of the bed-pan, nevertheless there will still be many patients who are condemned to use it. The writer did at one time design a bedstead in which the bed-pan was placed below the bed and moved into position by a lever rather like the breech-block of a gun. This, however, required a special mattress and draw sheet and was considered by the nursing profession to be too elaborate. It is essential therefore to redesign the bed-pan itself, which should be deeper and more stable. This is an unpleasant subject to discuss in print, but the comfort of our patients must always be our first thought and justifies calling attention to the matter.—I am etc.,

London, W.1.

MALCOLM DONALDSON.

Medical Photography

SIR,—In the concluding section of "Where are we Going?" Dr. Ffrangcon Roberts (March 13, p. 485) says that economics is a dismal science. But surely he is being a little too dismal. He is particularly unfortunate in his choice of clinical [sic] photography as a scapegoat. The present growth of medical photographic departments (the term "clinical" is too restricted to cover their work) has been brought about mainly by a widening realization of the value of visual methods in education. We in this country, with a few noted exceptions, had been lagging behind the United States in our use of visual methods of instruction, but during the late war we were compelled to increase the efficiency of our technique for the simple reason that the need for more rapid training was paramount. It was

shown time and again that the great majority learn better and faster by using their eyes than by using their ears. There is now a widespread desire among teachers to apply this wealth of experience to medical teaching in general, and I feel sure that Dr. Roberts would be the first to support anything which can lighten the almost intolerable burden of the present curriculum. Agreed that the facilities must be intelligently employed, but it is quite certain that the demands of teachers for the products of the department are wellnigh overwhelming, in spite of expansion.

Dr. Roberts does not give the sources of his quotations, but I can recognize them with the exception of the reference to radiology. The first article was widely felt at the time to be "castles in the air" and likely to frighten people away, and several writers said so. I can safely assure him that it does not represent the opinion of the majority of those connected with departments of medical photography. The statement that the staff will need a long and complete training needs no support. If the new qualification set up by the Institute of British Photographers, the examining board for which includes qualified medical men, is to mean anything, its standards must be high. And I have yet to find evidence that an expert in any branch of photography, or for that matter in anything else, can be made overnight. The quotation concerning cramped quarters is torn from its context, and does not suffice to convey the author's meaning. Would Pasteur, Thomson, and Hopkins have been any the worse for good accommodation? Surely this is merely a passion for what the Services used to call "doing it the hard way"?

Finally, I would suggest that the present increase in medical photographic departments in our teaching hospitals does not indicate an urge for expansion; the teaching staff are not all suffering from delusions of grandeur. It indicates only a very reasonable desire for high quality in recorded and instructional material, and a determination that those who provide it shall work under reasonable conditions. There is also every chance that it will lead incidentally to a much-needed improvement in the standard of pictorial and line work submitted to the journals for publication.—I am, etc.,

Manchester, 13.

ROBERT G. W. OLLERENSHAW.

Bone Conduction in Otosclerosis

SIR,—What is most urgently needed to-day in regard to the over-publicized fenestration operation for otosclerosis is a careful, sober, and dispassionate estimation of end-results. After Simson Hall had performed 200 operations he reviewed 118 of them only as suitable for analysis (*Journal*, 1946, 2, 647): as long ago as January, 1945, Lempert, of New York, published a series of 1,000 fenestration cases, and Shambaugh, of Chicago, recorded 930 cases in 1946. And here is Mr. Magauran reporting a case in the *Journal* (March 20, p. 569) six weeks after he had left hospital and only 12 weeks after his first (of two) fenestration operations, and apparently the patient's hearing was never examined with an audiometer before or after operation.

Otologists in general agree that two years (some optimists one year) is the period after which the hearing result from fenestration may be regarded as permanent. Suggit found in 1938 that there was an average fluctuation of 10 decibels in a group of stationary cases of otosclerosis when examined methodically with the audiometer. Psychological deafness is well recognized nowadays, though not many otologists have found as many cases as Canfield (1947) did in his war veteran patients, and there is undoubtedly a marked psychological element in many otosclerotics. As for bone conduction in otosclerosis, most otologists would, I think, agree with Tumarkin (1947) that the myth of increased bone conduction has long been exploded.—I am, etc.,

London, W.1.

R. SCOTT STEVENSON.

Brodie's Abscess

SIR,—In the interests of accuracy it seems desirable to add to the article by Messrs. Stanley Scott and Frank S. Preston (Feb. 14, p. 296) and to Mr. St. J. D. Buxton's letter on this subject (March 6, p. 472). The latter rightly points out that although Brodie saw the first of his cases for the first time in 1824 he did not actually publish anything on the subject in

Fig. 1

Fig. 2

WELL-LEG TRACTION

Using Gypsona P.O.P. Bandages

MARCH 6TH.—Patient aged 66, sustained transtrochanteric fracture of the left femur. (Fig. 1.)

MARCH 6TH.—Fracture reduced and fixed in modification of the well-leg traction technique. Using Gypsona, a snug-fitting plaster casing was applied and anchored to the uninjured leg (Fig. 3). X-ray showed good reduction, which was maintained satisfactorily without need for any change of plaster during the two months in which it was retained.

APRIL 30TH.—X-ray examination showed good position and good callus formation proceeding (Fig. 2).

COMMENT. This method obviates the necessity for pins transfixing the heel or tibia, it enables the patient to sit up in bed, and thus materially reduces the risk of hypostatic pneumonia and pressure sores. It is essential that during fixation of the cross struts the injured leg is pulled, and the well-leg pushed, so that the top of the plaster is firm against the tuber ischii.

These details and illustrations are of an actual case. T. J. Smith & Nephew, Ltd., of Hull, manufacturers of Gypsona P.O.P. and Elastoplast bandages, publish this instance—typical of many—in which their products have been used with success.

Fig. 3

DEEP DARK SECRET

Suffering in silence because of a natural reluctance to reveal any abnormal rectal condition, the patient with haemorrhoids is additionally inhibited by vague fears of major surgery and "the knife".

Having finally exposed his secret to the physician, the patient may frequently be spared further pain and discomfort by the use of Anusol* Haemorrhoidal Suppositories.

Providing relief through their decongestive and lubricating qualities, Anusol Haemorrhoidal Suppositories diminish pain, lubricate the ano-rectal mucosa and discourage "fear retention" followed by straining.

B.D.H. SEX HORMONES

for implantation

Sex hormone administration by implantation has many advantages over oral or parenteral treatment in those cases in which continuous action of the hormone is desired.

The need for frequent injections is eliminated and the natural continuous secretion of hormone is more closely simulated than is possible from injection even of esterified hormones in oily solution.

B.D.H. Sex Hormone Products are available in pellets for implantation as follows :—

	Price per pellet
OESTROFORM (œstradiol) 20 mg.	30s. 0d.
PROGESTIN B.D.H. (progesterone) 100 mg.	50s. 0d.
TESTOSTERONE PROPIONATE B.D.H. 100 mg.	42s. 6d.

THIOURACIL B.P.C. and METHYL THIOURACIL

In the Treatment of Thyrotoxicosis

The thyroid-depressant properties of Thiouracil and Methyl Thiouracil find useful application in the treatment of thyrotoxicosis and the pre-operative preparation of the thyrotoxic patient.

The administration of either substance by the mouth in cases of hyperthyroidism brings about an alleviation of nervous symptoms, a fall in basal metabolic rate, increase in weight and a general improvement in the clinical condition of the patient.

DOSE: Initially, a dose of 0.5-1.0 gramme daily, in divided quantities, is administered until clinical improvement is achieved. This is then reduced to a daily dose of 0.05-0.2 gramme and maintained at the lowest level compatible with the patient's well-being.

PACKINGS: Methyl Thiouracil and Thiouracil for oral administration are each issued in tablets of 0.05 gramme, 0.1 gramme, and 0.2 gramme, in containers of 100 and 500.

IMPERIAL CHEMICAL [PHARMACEUTICALS] LTD.

THE RIDGE, BEECHFIELD ROAD,
ALDERLEY EDGE, MANCHESTER

Ph.210

that year. However, he continues, "I find no record of him reporting this case prior to 1832." In fact, Brodie published this case and one other in a paper, "On Trephining the Tibia," in 1828 (*Lond. med. Gaz.*, 2, 70). These were described more fully, with a third case, in his paper of 1832; all three were repeated, with a further three, in the famous lecture of Nov. 19, 1845, together with a few miscellaneous cases not of this type of abscess.

As for the question of what is and what is not a Brodie's abscess, it seems reasonable to define it as a "chronic circumscribed pyogenic intramedullary abscess of bone." In fact Brodie's cases were all of the tibia, but it seems not unreasonable to use the term for a similar lesion occurring infrequently in other bones. Incidentally, although, of course, he gave no suggestion as to the aetiology, it is almost certain from his descriptions that these were pyogenic abscesses and not tuberculous disease of the bone as is sometimes stated.

It is a pity that Messrs. Scott and Preston give no references whatever to the authorities they quote, not even Brodie himself, whose papers they do not appear to have consulted. (The second and third of these are reprinted in full in *Medical Classics*, 1937-8, 2, 900 and 907). As Mr. Buxton states, it is important to know exactly what an eponymous authority actually said, and this not only to avoid the confusion to which uncertainty leads but also for the intrinsic merit of classical writings, in this case considerable.

I would add that this is not to detract from the clinical part of their paper, which I have no wish to criticize.—I am, etc.,

The London Hospital, E.1.

A. P. WATERSON.

Relief of Pain in Midwifery

SIR,—Dr. Anne M. Toms (March 6, p. 475) maintains that stretching of the perineum in the second stage of labour cannot be painless, her argument being that stretching of the skin of any other part of the body is painful and that the perineum is no less sensitive. She does not take into account the softening of the perineum that occurs during pregnancy and labour.

Stretching of the perineum in the non-pregnant woman is certainly very painful. The perineum is painful and tender for days following the stretching necessary, for example, before a dilatation and curettage is performed. I have had a dilatation and curettage.

I have also, however, had a normal, relaxed labour, after antenatal preparation as advocated by Dr. Grantly Dick Read. I had no drugs, but during the second stage I had absolutely no pain; and at no time then or in the puerperium was the perineum at all tender or painful.—I am, etc.,

Prestbury, Cheshire.

FLORENCE H. AUCKLAND.

National Hearing-aid

SIR,—The Government hearing-aid scheme seems to have been engendered in an emotional fervour on behalf of the deaf and to have swept on to its present state without adequate thought as to the objectives and the most efficacious way of achieving them. It has got entirely out of control and must fail to achieve its objective unless correctives are applied.

It presupposes that there are 400,000 deaf people in this country waiting anxiously for hearing-aids. Three-quarters of them have never seen a hearing-aid and would shrink from using one. Most of those who have inquired will refuse to use the Government aid when they see how bulky and complicated it is. The education of a deaf person to the point where he will use a valve hearing-aid takes a long time, and when knowledgeable he will demand and need only the best, with the right kind of personal attention.

The aid itself will give good results, though not as good as laboratory tests, due to the difficulties of maintaining high standards in mass production. It suffers from the handicap of its conception—a standard aid for all deaf people. There is no standard aid that is satisfactory for all. Success depends on a number of factors of very real importance to individual patients. The Report admits the unreliability of the crystal receiver which will be used with most patients. The alternative disk carphone with headband is ugly and inconvenient. No provision whatsoever is made for bone conduction. This is a striking omission.

The proposed method of supply through hospitals is unsuitable. A deaf person should be freed from the feeling that he is a hospital case. No hospital scheme can give the efficient service and thoughtful attention required to ensure success. The United States Veterans Administration, with long experience of hearing-aid supply, regards the after-fitting attention as more important than the instrument itself.

The New Zealand Government has given our own a lead in the provision they should make. As an alternative to a standard aid a grant of £15 is made towards the purchase of a commercial instrument. Our own Government should do no less. In order to avoid what they call "commercial exploitation" they have evolved a scheme which is costly and valueless. Surely the objective is that the deaf shall be helped to the utmost; as it is, they will be fobbed off with a utility instrument and a totally inadequate service. They will have freedom from payment, but they will lose freedom of choice and freedom of criticism, and they will not get good hearing.—I am, etc.,

London, W.1.

A. EDWIN STEVENS,
Governor, Director, Amplifier Ltd.

SIR.—According to the Medical Research Acoustic Committee's Report No. 261, "Hearing Aids and Audiometers," prototypes of the national hearing-aid now being manufactured were tested by 27 deafened persons, and Lord Walkden tells us in the House of Lords that these tests were each of three hours' duration. The following facts should be taken into account when considering the results of the Medical Research Council's tests.

(1) Post-war models of British commercial hearing-aids were not included in the Medical Research Council Acoustic Committee tests.

(2) Reputable British hearing-aid manufacturers are prepared to allow any of the deafened public a full week's unrestricted trial of their products under ordinary conditions of use before purchase need be considered, and during the trial the instrument can be compared with any other British or American aid available. The results of these tests will be different from those of three hours.

(3) Production models of British commercial post-war hearing-aids will without doubt compare favourably in efficiency, compactness, and appearance with production models of the national aid when available.

(4) The deafened public are not likely to remain satisfied for long with the Government free aid which has been made obsolete by British commercial hearing-aid manufacturers' latest models.

Secretary, the H.A.M.A. and
Society of Aural Technicians

Calories and Appetite

SIR.—The many controversial statements which have recently been made both in the medical press and Parliament have, to my surprise, considered the nutritional value of food solely in terms of calories (and occasionally vitamins). No mention is ever made of the quality of the food eaten.

Statistics completely ignore this aspect and naturally pay no attention whatever to whether the food is appetizing or not—it usually is not! Consequently much of the food statistically consumed is never eaten at all. It is ludicrous to make no distinction between good fresh food, well cooked, and stale unappetizing meals badly cooked. They may weigh the same (and calories are based entirely on weight), but they are not of the same use to us.

There is plenty of food in Britain, but mostly of inferior quality and far from tempting. That we survive is a tribute to our digestion.—I am, etc.,

London, W.2

A. M. GREEN.

Westmoreland Lodge

SIR.—Your readers will remember that in the *Journal* of Jan. 18, 1947 (p. 101), you kindly gave an account of a new venture of the Royal Medical Benevolent Fund—namely, the provision of a house for a number of our old ladies. I shall be grateful if you will now allow me to report the opening of Westmoreland Lodge.

In spite of the usual difficulties with licences, supply of builders' materials, and labour this charming house standing in its own grounds near Wimbledon Common has been completely renovated and adapted to the needs of twelve of our beneficiaries. Each lady has her own bed-sitting room equipped

with either gas or electric fires and a small set-up for minor cooking, while on each floor there is generous provision of all necessary facilities. In addition there is a lovely room on the ground floor in part dining-room and in part sitting-room, with a sun-lounge overlooking the garden.

Fifteen years ago the late Dr. A. Holdsworth Davies bequeathed to the Fund his house at Bournemouth and the whole of the estate. He expressed the wish that his house should be used as a home for elderly people, but wisely left the Fund free to use its own judgment and free of restraint. The late Sir d'Arcy Power and I visited the house and realized it was quite unsuitable for this purpose. Accordingly the house was sold and the Holdsworth Davies estate has been administered as a separate entity in our accounts and the income used as nearly as possible to help those whom Dr. Davies had had specially in mind in the hope that one day his wish might be fulfilled.

To-day something perhaps even better than he visualized is a vital concern, and I have delayed writing until a few weeks have elapsed and we knew that our ladies were happily settled in. Two other friends have helped materially in furnishing and equipping Westmoreland Lodge. Under the will of Miss L. H. Wiltshire the Fund received a most valuable gift of furniture in addition to a substantial sum of money. Mrs. Parry has also helped us with a most generous donation in memory of her late husband. These gifts have enabled us to furnish the communal dining- and sitting-room and to provide other attractions which would have been difficult without them.

I think I may claim that this venture, the merits of which are so self-evident, required considerable courage on the part of the committee of management in embarking upon so ambitious a project in such difficult days. We are amply repaid by the sense of security and comfort and happiness of our residents. Their feelings are summed up in the words of one of them thus: "I do like opening the front door of this house because I know I am coming in to such a happy atmosphere." We are also repaid by the approval and encouragement given to us by so many members of the profession.

This letter is a progress report, but the success of Westmoreland Lodge leads us on to other thoughts. Might we not think of a similar house for men, and should we also provide for the sick and bedridden? To a certain extent the answers to these questions depend upon the reaction of the profession to our work. This is not a begging letter, but in the past twenty years the Fund has made enormous strides and Westmoreland Lodge is a new and important venture. The committee would like to know that the profession whole-heartedly approves the work we are doing as trustees of their benevolence.—I am, etc.,

R. M. HANFIELD-JONES,
Chairman,
Committee of Management,
Royal Medical Benevolent Fund.

POINTS FROM LETTERS

Resign on April 1

Dr. G. H. URQUHART (St. Annes-on-the-Sea, Lancs.) writes: The medical profession's idea of a sound national health service is that the health of the nation should be the main consideration. This could quite readily be accomplished through "grants in aid" by the Treasury to all hospitals and universities. The medical profession in other respects can best manage its own complex affairs without political interference. In order to achieve our aims we shall have to fight, and in order to fight, funds are necessary. We have some, but not enough; so in order to conserve and reinforce these the general practitioners should resign *en masse* from the N.H.I. on April 1 instead of being pushed out on July 5. Let them then transact treatment for patients on a cash basis only (no accounts) that will keep the practitioners in funds meanwhile. On and after April 1 let there be no issue of any kind of certificates other than birth, infectious diseases, and death. The B.M.A. fighting fund could thus be utilized wholly for the purpose of supporting those who have not the above advantages at their disposal but yet must live. . . .

Prescribe Quickly

Dr. W. H. TATTERSALL (Reading) writes: The 1946 National Health Act—not yet eighteen months old—seems to be threatened with what might be called "infantile paralysis." At any rate 75% of our profession agree about it—a degree of unanimity rare among doctors. It hardly matters now whether this condition is the result of a birth injury following a long labour or whether the midwife

should have summoned medical aid to the confinement. No, the problem now is to prescribe, and *prescribe quickly*, such treatment as is necessary to enable this Act to recover from its palsies and find a respected place on the statute book. . . .

Design of N.H.S. Cards

Dr. G. B. BOWATER (Birmingham) writes: If under the N.H.S. patients are still to possess medical cards, I would suggest that they be modified to include a space in which the surgery hours and half-day of the doctor could be entered.

Doctors' Wives

Mrs. W. GORDON (Poole) writes: In view of the recent comments in the *Journal* regarding the unpaid work of doctors' wives after July 5, would any useful purpose be served if we (the wives) called meetings either privately or through the auspices of the local Branches of the B.M.A. throughout the country? We could then air our views, grievances, and suggestions, and present our case to the Minister, and so ensure that he realizes that if we down tools (the telephone) he must either provide our husbands with competent petrolonists or secretaries or pay us for doing the job.

Petrol Rationing

Dr. H. S. GRIFFITH (Wolverhampton) writes: For thirty years I have been giving certificates which have always been accepted without hesitation, but when it is a matter of my own petrol requirements, what a fall is there, my countrymen! No longer am I the omniscient sage whose word can be trusted, as it is regarding your wife's visceroptosis, your invalid aunt's fuel requirements, or as to whether your grandpa is a genuine tobacco addict. No, I think my application must be included in the "obvious twisters" batch and given to a clerk with the instruction to "dock 'em 50%." Anyway, that is the result when I apply (and reapply) for three-quarters of the amount allowed to my predecessor in this practice.

Fugue after Mepacrine Administration

A physician writes from Pakistan: The account by Dr. D. R. Macdonald (Dec. 13, 1947, p. 959) of two cases of fugue after mepacrine prompts me to cite my personal experience with the drug. Towards the end of May last I had a 4-day course of mepacrine, 4 tablets a day. This finished on May 30. On the afternoon of the following day, as I was writing a couple of letters, I suddenly felt that I could not easily write a full sentence; I had to think out each word separately. A few minutes later restlessness with mental and physical overactivity followed. For instance a chair slightly out of line with others, a book placed not in a straight line on the table, and such other very minor things began to irritate me. I perceived that something was going to happen. I called in my son, a medical student, to warn him of the possibility of mepacrine psychosis. In the course of a few minutes the condition became distinctly worse. I was agitated and apprehensive. I lost reserve. The speech was at first hurried, but soon I could not find suitable words. However, I continued to talk in a non-stop manner. Old memories came up to the forefront, and ideas ran across the mind with great speed. However, none of the higher faculties was affected. The acuteness lasted about three hours. By then I felt exhausted and literally sank upon my feet. Shortly thereafter, suddenly, I felt that the worst was over. I took rather heavy doses of sedatives and hypnotics. Next morning I woke up exhausted, but otherwise practically normal. For a week thereafter I was mentally below my own normal, though I carried on my usual medical practice. For instance, while driving my car on a familiar road with turns I would not realize which turn would be the next until I actually reached it, when I would take the correct turning.

My age is about 56. Otherwise I have a very good personal and family history. I had never taken mepacrine before, though I had prescribed it thousands of times with no mishap, except once when a short psychosis occurred in a rather unstable lady.

Sweet Urine Containers

Dr. W. E. McCULLOCH (Kingston, Jamaica) writes: This case illustrates the necessity of being careful about the bottles that are used to send samples of urine to the laboratory. The early morning urine of a patient of mine was ++++ for glucose on two successive days, and this was totally unexpected. My laboratory technician then noticed that the stoppers of the bottles were labelled "honey." A third morning sample sent in a soda-water bottle was negative and the urine has continued to be free from sugar.

The husband assured me that all bottles had been boiled before use, and he is a careful man. A third honey bottle was obtained. It had also been boiled and was dry. Washings in distilled water were negative for glucose. The cardboard lining to the stopper was strongly positive for glucose. The astonishing thing is that these honey bottles can be dated. They were received from England as samples over ten years ago, and were washed and put away as used. The honey absorbed in the cardboard washers has been there for over ten years; no crystallized sugar was visible, yet the glucose reaction was very strong.

Obituary

E. WAYMOUTH REID, Sc.D., M.B., F.R.S.

Prof. E. Waymouth Reid, who occupied the chair of physiology at University College, Dundee, for forty-six years, died on March 10 at his home in Edinburgh, where he had been living since his retirement. He was 85, and although he had been confined to bed for several years he had been in his usual state of mental alertness until three days before his death.

Edward Waymouth Reid was born in Canterbury, where his father was in practice as a surgeon. He went from Sutton Valence Grammar School to Cambridge with an open classical scholarship in 1879. He took a first-class in human anatomy and physiology in the natural sciences tripos in 1883, and after a period at St. Bartholomew's Hospital he graduated M.B. He was assistant electrician at St. Bartholomew's Hospital in 1885, and subsequently demonstrator of physiology in St. Mary's Hospital Medical School. He became assistant lecturer on physiology at St. Mary's two years later and was appointed professor of physiology at University College, Dundee, in 1889. He was then only 27, and he taught generation after generation of medical students at Dundee until his retirement in 1935. At the relatively early age of 36 Waymouth Reid was elected a Fellow of the Royal Society in recognition of the contributions he had already made to physiology, and six years later he was made an honorary Sc.D. by the University of Cambridge.

Prof. Reid was one of the first workers in Great Britain to suffer from x-ray burns. Only a few months after Roentgen's discovery he constructed an x-ray apparatus and in the course of his experiments received a superficial skin injury which he thought might be due to exposure to the rays. To settle this point he deliberately exposed himself for a longer period and received a burn of which he carried the scar for the rest of his life. During his tenure of the chair some 60 papers were published from the Physiology Laboratory of University College, Dundee. His work on serum absorption was important, and so was his preparation of crystalline haemoglobin. He was the first Dean of the Faculty of Medicine in the University of St. Andrews and did much valuable work in connexion with the early organization of a laboratory service for the use of general practitioners in the Counties of Fife, Forfar, and Perth, a service which was later taken over by the University Court. The work he had done for University College and St. Andrews University was recognized soon after his retirement by the conferment of the degree of LL.D.

Prof. Reid had been a member of the British Medical Association for just under sixty years. He was vice-president of the Section of Physiology at the Annual Meeting in 1898, and he was president of the Dundee Branch in 1903-4. He was for a time one of the editors of the *Journal of Physiology*, and he had acted as examiner in physiology for the Royal College of Surgeons of England, the University of Cambridge, and the Royal College of Veterinary Surgeons. Waymouth Reid was popular with his students and was an enlightened and enlightening teacher. His recreations included photography and horticulture, and he had a keen sense of humour. His wife died many years ago, and he is survived by a son and three daughters.

H. W. GARDNER, M.B.E., M.D., F.R.C.P.

Dr. Henry Willoughby Gardner died peacefully at his home in Church Stretton on Feb. 27, at the age of 86. He was educated at Charterhouse and St. Bartholomew's Hospital, qualified in 1885, graduated M.B. in the following year, and proceeded M.D. in 1888. He was elected F.R.C.P. in 1917. He was a house-physician and resident obstetrical assistant at St. Bartholomew's Hospital before taking up an appointment as a Government medical officer in New South Wales.

Returning to England, he joined Dr. Withers in general practice in Shrewsbury. After some years, however, he decided to do consulting work only and found his real vocation as honorary physician to the Royal Shropshire Infirmary, the Shropshire Orthopaedic Hospital, and the County Sanatorium. Interested in all branches of medicine, he was always receptive to new ideas and recent advances. Dr. Gardner had been a member of the British Medical Association since 1892,

and was a president of the Shropshire and Mid-Wales Branch in 1913 and 1919, and a member of the Branch Council in 1901, and from 1905 to 1917. When the Association met at Birmingham in 1911 he was vice-president of the Section of Therapeutics, and he had previously represented his constituency at the Annual Representative Meetings at Leicester in 1905 and at London in 1906. His other interests were many, and included gardening, golf, and fly-fishing, at which latter he was quite an adept. He had the misfortune to lose his wife and only son some years ago. As evidence of his great and abiding interest in the Royal Shropshire Infirmary he has left his house at Church Stretton to that institution to be used as a rest home for the nurses. He was much interested in the present phase of medical politics, and, it might be added, was considerably perturbed at the outlook. In recognition of his work during the 1914-18 war he was made a member of the Order of the British Empire, but he will remain long in our minds as a man of charming personality who did his life's work well and whose main characteristics were honesty of purpose and a well-balanced mind.—J.A.1.

R. F. YOUNG, M.C., M.B., B.Chir., F.R.F.P.S.

Mr. Roy Frew Young, one of the best-known surgeons in Glasgow, died on March 12. Mr. Young was educated at Glasgow Academy and Sedburgh School, and at the Universities of Cambridge and Glasgow. After graduating B.A. at Cambridge and M.B., Ch.B. at Glasgow in 1909 he was appointed extra dispensary surgeon at Glasgow Western Infirmary, becoming in turn dispensary surgeon, assistant surgeon, and visiting surgeon. On his retirement in 1944 he was appointed honorary consulting surgeon. He was also a lecturer in clinical surgery at the University of Glasgow; consulting surgeon to the Vale of Leven Hospital; and he was associated with the Bellahouston Hospital and with the Royal Alexandra Infirmary at Paisley. In the 1914-18 war he served with the R.A.M.C. as a surgical specialist with No. 14 General Hospital in France. He was awarded the M.C. and twice mentioned in dispatches. As well as being the convener of the medical committee of the Glasgow Western Infirmary, he sat on the board of managers as representative of the Royal Faculty of Physicians and Surgeons of Glasgow, of which he became president in 1940. Last year the University of Glasgow conferred on him the honorary degree of LL.D., and it was barely a month ago that he retired from the board of managers of the Infirmary on the grounds of ill-health.

Roy Young was a good athlete in his younger days. He was president of the rugby football club at Glasgow University, and subsequently did much to encourage student athletics. He was a good teacher and a good surgeon, always telling his students that the operation was only a part, and perhaps not the most important part, of the surgeon's work. He insisted on the most careful pre-operative investigation and always devoted a great deal of attention to after-care. His counsel was widely sought, and he was ever ready to give advice on personal problems or on more general matters. A man of strong convictions, any cause he espoused was advocated with singleness of purpose and enthusiasm tempered by sound judgment. His personal charm and his lively sense of humour were potent factors in gaining acceptance for his views.

C. C. HEYWOOD, M.A., M.B., M.R.C.P.

Dr. Charles Christopher Heywood, who died at his home in Alderley Edge on March 10 at the age of 82, had been associated for 43 years with the Manchester Children's Hospital, Pendlebury, and he was also for many years consultant physician to the Salford Royal Hospital.

Charles Christopher Heywood, a son of the Rev. H. R. Heywood, vicar of Swinton, was educated at Harrow and Trinity College, Cambridge. He graduated M.B., B.Ch. in 1890 and took the conjoint diploma in the same year, and the M.R.C.P. in 1904. He was house-surgeon at the Salford Royal Hospital and later clinical assistant at St. Thomas's Hospital. Dr. Heywood then returned to Manchester as medical officer to the Manchester Children's Hospital, and at the same time acted as lecturer in physiology for the Salford Technical Institute. Later he became the senior physician at the Manchester Children's Hospital, and, apart from his work there and on the staff of the Salford Royal Hospital, he was

consulting physician to the Manchester Warehousemen and Clerks School, Cheadle Hulme, and examiner in physiology and hygiene to the Union of Lancashire and Cheshire Institutes. He was also consulting physician to Chetham's Hospital and to the Alderley Edge Cottage Hospital. He was for nine years an officer of the 2nd V.B. Manchester Regiment and the 6th Batt. Manchester Regiment.

Dr. Heywood's skill as a paediatrician, his sense of humour, and his kindness soon made him well known and well liked. He contributed a number of papers to the medical journals on the diagnosis of early rickets; on serous pleural effusions in children; on Calmette's tuberculin reaction; and on similar subjects.

Dr. WADHAM BRUCE WINCKWORTH died on Feb. 20 at the age of 79. At the time of his retirement ten years ago Dr. Winckworth was the senior practitioner in Taunton, where he had practised for more than forty years. He was born in London, and educated at Westminster School and at the Westminster Hospital. He qualified M.R.C.S., L.R.C.P. in 1893, and was a house-physician at the Westminster Hospital before settling in Taunton in 1895. He began practice with the late Dr. Samuel Farrant, and after some years set up his own practice, in which he remained until he was joined by his son, Dr. R. F. Winckworth, in 1935. His son is now in orthopaedic practice, and Dr. Fleming and Dr. Knowles have for many years been continuing the practice which the elder Dr. Winckworth founded. From 1923-33 Dr. Winckworth was on the honorary staff of the Taunton and Somerset Hospital, and after his retirement he continued to serve as chairman of its nursing committee. He was chairman of the West Somerset Division of the British Medical Association in 1932-3, and he was also an active member of the St. John Ambulance Association, for many years coaching the Taunton G.W.R. teams. He leaves a widow, two sons, and three daughters.

Dr. JOSEPH JOHN CLARKE, a justice of the peace for Essex and formerly medical officer of health for Walthamstow, died at his home in Hove on Feb. 24 at the age of 86. Dr. Clarke was previously in private practice in Walthamstow in partnership with his brother. He was educated at Queen's College, Cork, and the Middlesex Hospital, qualifying in 1894 and obtaining the diploma in public health in 1898. He was appointed part-time medical officer of health to the Walthamstow urban district council in 1898, and whole-time medical officer of health in 1906, retiring on pension in 1930. During this period Dr. Clarke built up a public health service in Walthamstow which compared more than favourably with that in any comparable area. In particular he was largely responsible for the erection of a fine infectious disease hospital, and this included the first cubicle block ever built in this country. The idea followed a visit to Paris, and the plan of this cubicle block was for many years a feature in the public health textbooks. This block is still actively functioning and has been in every way satisfactory for more than forty years. Dr. Clarke also sponsored an up-to-date welfare centre in Markhouse Road and the provision of specialist facilities in connexion with school health services. He will be remembered by his colleagues and friends for his charming Irish personality and his readiness to help in all cases of misfortune. Recently his period of retirement had unfortunately been marred by ill-health.—A. T. W. P.

Dr. PERCY LUND POLLARD died on Feb. 25 at the age of 66 after a short illness. Dr. Pollard was educated at Manchester, and graduated M.B., Ch.B. in 1906. He went to the Royal Halifax Infirmary as a house-surgeon and remained there until 1910, when he went into general practice. It was during the years as a house-surgeon that he became interested in surgery, and the opportunity to practise came with the 1914-18 war, when he joined the R.A.M.C. and did excellent work on the surgical side, for which he was mentioned in despatches. In 1919 he was appointed assistant honorary surgeon at the Royal Halifax Infirmary. His chief interests lay in general surgery and in gynaecology. Though running a busy general practice he found time to spend hours a day at the Infirmary. He was twice chairman of the Halifax Division of the British Medical Association, and was president of the Yorkshire Branch in 1928-9. He was senior surgeon at the Infirmary by 1939, and he became medical superintendent in charge of air-raid precautions and of E.M.S. cases, and did much valuable work. In 1943 he had to undergo a major operation, and but for his indomitable spirit would never have returned to duty. Early in 1947 he retired from the active surgical staff and became a consultant surgeon. On the occasion of his retirement the

Board of Governors and the medical staff presented him with a silver salver to mark many years of good, faithful service. Unfortunately P.L.P., as he was known to his friends, was not to enjoy a long retirement, for after a short illness he died. His many friends and colleagues extend their sympathies to his widow and two sons.

Medical Notes in Parliament

National Health Service

On March 16 Mr. BEVAN gave an assurance that names on existing panel lists would be automatically transferred to the list of their present doctor if he entered the National Health Service unless either the doctor or the patient objected.

On the same day Mr. BEVAN assured Mr. PARKIN that doctors joining the National Health Service in July who had not reached their 56th birthday would be eligible to complete ten years' service and qualify for superannuation and retirement allowance.

Mr. BEVAN stated on March 18 that provision was made in the estimates for the current financial year, 1947-8, for 350 extra staff to deal with additional work resulting from the National Health Service Act. For the next financial year, 1948-9, it had been found necessary to provide for a further 320. Nearly half of these additional 670 were required as a result of the provisions in the Act for superannuation benefits for those taking part in the different branches of the new Health Service. Of the remainder, most are required for other financial work in connexion with the Act. He added that the total staff to be employed at the headquarters of the fourteen Regional Hospital Boards at the date when the Act came into force would be about 600. Of these a large proportion would not be extra staff but would have been transferred to the service of the Boards from local authorities and other bodies.

Sir WAVELL WAKEFIELD asked on March 18 if Mr. Bevan proposed under the National Health Scheme that medical practitioners should be entitled to a five-day week, with extra pay for overtime, Sunday work, and night work, together with danger money when attending cases of infectious disease.

Mr. BEVAN replied that the terms of service for general practitioners under the National Health Service were set out in the National Health Service (General Medical and Pharmaceutical Services) Regulations, 1948, which were now before Parliament.

Nutritional Surveys in Germany

Mr. MAYHEW, for the Foreign Office, stated on March 15 that late last autumn members of the Combined Nutritional Committee reported that the nutrition of the urban population in the Western Zones of Germany had improved during the previous six months. Famine oedema was very rare, and adult body weights had not declined. These findings had been confirmed by a survey carried out by representatives of the Medical Research Council in November.

Food Facts

Dr. SUMMERSKILL circulated on March 15 the following statistics of the daily intake of foods in the United Kingdom per head during the first half of 1947:

Protein—		
animal	45.2 g.
vegetable	43.0 g.
total	88.2 g.
Fat (from all sources)	108.3 g.
Visible fat (butter, margarine, lard, etc., fat content)	42.1 g.
Total energy value	2,870 calories.

Purchase Tax

Sir STAFFORD CRIPPS estimated on March 10 that receipts of purchase tax for medicines, drugs, disinfectants, toothbrushes, and toothpaste were in the region of £15,000,000 a year. He promised to reconsider, before the National Health Service Act was brought into force, the taxation of such goods.

Theft of Dangerous Drugs.—The records of the Metropolitan Police show that 4 losses and 60 thefts of dangerous drugs from doctors were reported in 1947.

Streptomycin.—Production of streptomycin in the United Kingdom on a small scale will start shortly, but imports are still necessary. Stocks on Sept. 1, 1947, were 25 kg. and on March 1, 36 kg.

The *proteolysed* extract of liver for parenteral use

NEO-HEPATEX

PROTEOLYSIS—Original research in the Evans laboratories has shown that a better liberation of active principles from protein complexes, and an enhanced therapeutic potency can be obtained by the application of controlled proteolytic enzyme digestion to liver in the manufacture of anti-anæmia preparations.

POTENCY—Each batch is clinically tested before issue to ensure that a dose of 2.0 c.c. every fourteen days will restore the blood picture to normal in the average uncomplicated case of pernicious anæmia. A maintenance dose of 2.0 c.c. per month is usually adequate.

Vasodilatation

There is considerable evidence of the outstanding value of Cardophylin in producing vasodilatation. The coronary vasodilatation is manifested in an increased coronary blood flow and a beneficial effect on the myocardium; the renal vasodilatation is indicated by the powerful diuresis. It also causes bronchodilatation.

COMBINED PROTECTION WITH 3 INJECTIONS

By the use of 'Wellcome' brand Diphtheria-Pertussis Prophylactic D.P.P., children may be immunised against the two diseases in a course of three injections. The product contains Diphtheria Prophylactic A.P.T. plus Whooping Cough Vaccine (Alum Precipitated). Immunisation with 'Wellcome' Diphtheria Prophylactic A.P.T. has markedly reduced the incidence of and mortality from diphtheria. Although Whooping Cough Vaccine does not confer a degree of immunity comparable with that induced by diphtheria prophylactics, wide experience amongst clinicians indicates its value in reducing the incidence and severity of the disease.

'WELLCOME'— DIPHTHERIA - PERTUSSIS PROPHYLACTIC D.P.P.

Containers of 1 c.c. (2s. 3d.) and 10 c.c. (12s. 6d.)
(Subject to professional discount)

SUPPLIED BY
BURROUGHS WELLCOME & CO. (The Wellcome Foundation Ltd.) LONDON

In every language, 'A' and 'D' are momentous members of the medical alphabet. The maintenance of health and the re-establishment of well-being after illness are intimately linked with the state of vitamins A and D nutrition. During infancy and childhood these same nutritional factors, above all others, secure orderly growth and development. And, almost everywhere, Adexolin is synonymous with these two vitamins—the highly concentrated, refined preparation, acceptable even in the hottest climate. Adexolin Liquid is effective in drop doses: twelve drops daily for the baby . . . twenty drops for the adolescent . . . and up to sixty drops for the debilitated adult. Indeed, whatever the indication for additional vitamins A and D, Adexolin Liquid may be prescribed at the precise dosage to meet the patient's needs.

ADEXOLIN *the cosmopolitan*

LIQUID

Each $\frac{1}{2}$ minim drop contains approximately
350 i.u. vitamin A and 60 i.u. vitamin D

AMECHOL

TRADE MARK BRAND

Acetyl-β-methylcholine

Having a more pronounced action on the cardiovascular system, "Amechol" is of particular value in the treatment of vasospastic conditions of the extremities, including Raynaud's disease and chronic ulcers; also indicated in congenital megacolon, auricular paroxysmal tachycardia and chronic rheumatoid arthritis.

MORYL

TRADE MARK BRAND

Carbachol

Employed with marked success in post-operative urinary retention and paralytic ileus, "Moryl" is also effective in hypotonia, anxiety neurosis and in peripheral vascular diseases particularly if due to vasospasm. Also employed locally in atrophic rhinitis and as a miotic in glaucoma.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended March 6.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are: or: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

|| Includes puerperal fever for England and Wales and Eire.

Discussion of Table

In England and Wales infectious diseases were more prevalent during the week, and increases in incidence were recorded for measles 1,476, whooping-cough 436, scarlet fever 359, acute pneumonia 62, dysentery 39, and cerebrospinal fever 11.

The largest increases in the notifications of measles were London 371, Middlesex 259, Lincolnshire 181, Lancashire 161, Warwickshire 141, Surrey 130, and Northamptonshire 128. An increase in the incidence of whooping-cough occurred throughout the country; the largest rises were Essex 63 and London 59.

Notifications of scarlet fever increased in every region except the south-western and eastern counties; the chief increases were: London 55, Glamorganshire 44, Middlesex 22, and Warwickshire 32. A small rise in the incidence of acute pneumonia was recorded in most areas, but there were no large variations in the local trends. The chief features of the returns for diphtheria were increases in Lancashire 10 and London 8.

The largest centres of dysentery were Yorkshire West Riding 55 (Sheffield C.B. 25), Lancashire 47 (Preston R.D. 11), and London 22. One-quarter of all the cases of cerebrospinal fever were notified in two cities—Liverpool C.B. 7 and Birmingham C.B. 5. The only counties with more than one notification of acute poliomyelitis were Warwickshire 4 (all from Birmingham C.B.), Middlesex 4, Lancashire 3, London 2, and Surrey 2.

In Scotland there were increases in the incidence of measles 43, diphtheria 22, and cerebrospinal fever 22, and decreases in the notifications of dysentery 28 and scarlet fever 10. In Glasgow the notifications of cerebrospinal fever rose from 10 to 27. The rise in the incidence of diphtheria occurred in the western area. Only 6 cases of dysentery were notified in Edinburgh compared with 23 in the preceding week.

In Eire the chief features of the returns were increases in scarlet fever 22 and whooping-cough 26 and a decrease of 58 in the notifications of measles. A small increase in the return for scarlet fever and for whooping-cough occurred in most areas.

In Northern Ireland there was an increase of 14 in the notifications of scarlet fever. This disease is at the highest level since the beginning of November.

Week Ending March 13

The notifications of infectious diseases for England and Wales during the week included: scarlet fever 2,027, whooping-cough 3,418, diphtheria 173, measles 8,449, acute pneumonia 933, cerebrospinal fever 55, acute poliomyelitis 20, dysentery 213, paratyphoid 3, and typhoid 4.

Medical News

London Consultants Liaison Committee

The first formal meeting of the London Consultants Liaison Committee was held on March 16 at B.M.A. House. Representatives were present from the London teaching hospitals, the Association of Non-teaching Hospitals, the Association of Municipal Specialists, the B.M.A. Consultants and Specialists Standing Committee, and the Marylebone Division of the B.M.A. It was proposed, seconded, and unanimously agreed that such a committee should be formed, and that the terms of reference laid down by the B.M.A. Council's letter of Feb. 20 be adopted.

To establish and maintain liaison between the consultants and specialist staffs of the London hospitals and the B.M.A. in order to unify and consolidate consultant and specialist opinion on the National Health Service Act, 1946, within the policy of the profession as a whole.

The following officers were elected: Chairman, Lord Horder; Vice-Chairman, Sir Reginald Watson-Jones; Hon. Secretary, Mr. Eric Steeler.

The following resolution was proposed and passed unanimously:

That the Committee considers it desirable to investigate the present Act with respect to the privileges and restrictions of the consultant and specialist section of the profession, and that the best possible legal opinion be obtained to that end.

U.C.H. Scholarships

University College Hospital Medical School is offering two Goldsmid Entrance Scholarships entitling the holder to the final course of medical study, one Goldsmid Entrance Exhibition entitling the holder to a reduction in fees of £126 for the final course of medical study, and the Filmer Entrance Scholarship in Pathology entitling the holder to a reduction in fees of £123 for the final course of medical study. Further scholarships, medals, and prizes to the value of £1,000 are awarded annually. Full particulars may be obtained from the Vice-Dean.

Cost of N.H.S.

The estimated cost in the first nine months of the National Health Service is £149,675,000, according to the Civil Estimates published on March 20. The hospital, specialist, and ancillary services in England, Scotland, and Wales will cost £120,606,500; services provided by the local authorities, £4,050,000; general medical and dental services, pharmaceutical and supplementary ophthalmic services, £56,072,500. Compensation for loss of right to sell practices is estimated to be £4,800,000, and central purchase of equipment to be £7,505,000.

Exhibition of Medical Photography

The Medical Group of the Royal Photographic Society of Great Britain has arranged an exhibition of medical photography to be held at the Royal Society of Medicine (1, Wimpole Street, London, W.) from May 24 to 29. Entries must be submitted by April 24. Further particulars may be obtained from the honorary secretary of the group at 16, Prince's Gate, London, S.W.7.

Whitley Council Machinery

It is proposed to set up nine functional councils and a general council, as well as a Scottish council for special conditions in Scotland. The proposed functional councils are as follows: medical, dental, pharmaceutical, optical, two for professional and technical staffs, one each for nurses and midwives, administrative and clerical, and ancillary staffs. They would deal with questions of remuneration and the conditions of employment of people within the functional group concerned. The general council would deal with problems affecting more than one functional group.

Medical Certification

A preliminary draft of medical certification arrangements under the National Insurance Act has been issued and submitted to the National Insurance Advisory Committee. The regulations provide for five incapacity certificates: (1) A first certificate, to be issued when the patient falls ill. (2) An intermediate certificate, to be issued within seven days of the first certificate. (3) A special intermediate certificate, to be issued after 28 days, if the incapacity is likely to continue for a long period. (4) An intermediate convalescent certificate, to be issued after 28 days when the patient will remain incapable of work until after a period of absence from home during convalescence. (5) A final certificate, to be issued when the patient is again fit for work. Two certificates to be given by a doctor or midwife are also described, noting details of when the woman may expect to be confined and when she was delivered.

Scottish Hospitals Excepted from the N.H.S.

The Department of Health for Scotland has notified Roman Catholic hospitals and institutions that they will not be required in the N.H.S. Contractual arrangements will be made between Regional Hospital Boards and institutions.

Public Opinion on the N.H.S.

In a "Gallup Poll" conducted by the *News Chronicle* to test public opinion, 61% considered that the new Health Service "is a good thing." Sixty-four per cent of those questioned said they had some idea what the dispute is about between Mr. Bevan and the B.M.A., and in reply to the question, "In the main would you say that your sympathy is with the doctors or against the doctors?" 30 of these said "with," 28 said "against," and 6 said "don't know."

Czech Medical Trade Union

Since the Communist coup in Czechoslovakia, the Czechoslovak Medical Association has been declared a trade union, according to *The Times* of March 8.

COMING EVENTS**Chesterfield Medal Examination**

The Chesterfield Medal examination in dermatology will be held at St. John's Hospital for Diseases of the Skin, 5, Lisle Street, London, W.C., on Wednesday and Thursday, April 7 and 8, and Friday, April 16. The fee for candidates is £3 3s.

Medical Exhibition

The Southern Counties Medical Exhibition will be held at the Polygon Hotel, Southampton, on April 20 to 22. A number of well-known drug manufacturers are exhibiting, and some medical films will be shown each day in the afternoon.

Aslib

A study group on special librarianship will be held at the Library Association, Chaucer House, Maltraverse Place, London, W.C.1, on April 13-17. Applications should be sent as soon as possible to Aslib, 52, Bloomsbury Street, London, W.C.1.

SOCIETIES AND LECTURES**Wednesday**

INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY, 330, Gray's Inn Road, London, W.C.—March 31, 11.30 a.m. "Plastic Surgery," by Prof. T. Pomfret Kilner.

ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE, 28, Portland Place, London, W.—March 31, 3.30 p.m. "The Home Nursing of Children," by Miss Dorothy A. Lane, R.S.C.N.

Thursday

ROYAL PHOTOGRAPHIC SOCIETY.—At 16, Prince's Gate, London, S.W., April 1, 7 p.m. Medical Film Evening.

ROYAL SANITARY INSTITUTE.—At Guildhall, Northampton, April 1, 10 a.m. "Control of Infection in Day Schools," paper by Dr. C. M. Smith. "The Water Supply of Northampton," paper by Dr. C. G. Payton.

Friday

KENT AND CANTERBURY HOSPITAL, Canterbury.—April 2, 5 p.m. Monthly clinical meeting.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—At Leeds General Infirmary, April 2, 8.30 p.m. Annual meeting. "Some Diseases of People," by Dr. T. Main.

WHIPPS CROSS HOSPITAL MEDICAL SOCIETY, Whipps Cross Hospital, London, E.—April 2, 8.30 p.m. "The Modern Treatment of Venereal Diseases," by Dr. F. G. MacDonald.

APPOINTMENTS

Sir Alexander Fleming, F.R.S., and Sir John Boyd Orr, F.R.S., have been appointed members of the Scottish Council for Health Education.

HOLDERNESS, G. P., M.B., Ch.B., D.P.H., Full-time Medical Officer for New County Health Division of Aireborough, Horsforth, and Pudsey, Yorkshire.

LONDON COUNTY COUNCIL.—The following appointments in the Council's mental health services are announced at the hospitals indicated in parentheses. Assistant Physicians: H. R. Rollin, M.D., D.P.M. (Horton); A. S. Thorley, M.D., D.P.M. (Sutton).

MENEL, CHARLES, M.D., F.R.C.P., Emeritus Professor in Child Life and Health in the University of Edinburgh, has been elected to the Board of Managers of Edinburgh Royal Infirmary, in place of Dr. John Orr who has resigned.

PARKER, W. S., M.B., Ch.B., D.P.H., D.I.H., Medical Officer of Health, Cromer U.D.C., North Walsham U.D.C., Sheringham U.D.C., and Erpingham R.D.C., and Medical Officer, East Norfolk Joint Isolation Hospital.

THOMPSON, J. D., M.B., B.Ch., Director of Department of Physical Medicine, Redhill County Hospital, Edgware.

BIRTHS, MARRIAGES, AND DEATHS**BIRTHS**

Ferguson.—On March 10, 1948, to Joan M. Ferguson (née Thomson), M.R.C.S., L.R.C.P., wife of Matthew Ferguson, of 17, Townsend Crescent, Kirkcaldy. Five, a daughter.

Howkins.—On March 14, 1948, at 9, Lansdowne Road, Wembley, to Lena, wife of John Howkins, M.S., F.R.C.S., a daughter—Jane.

Raymond.—On March 7, 1948, at University College Hospital, to Dr. Joan Raymond, wife of Dr. Michael Raymond, a daughter.

Tate.—On March 13, 1948, at St. Mary's Nursing Home, Nottingham, to Betty (née Wilks), wife of Dr. Hugh Tate, M.B.E., a brother for Richard—Simon George.

MARRIAGES

Adam—Ross.—On March 12, 1948, at St. John's Episcopal Church, Forres, by the Rev. Canon Cecil Lake, T.D., J. C. Adam, T.D., M.B., Ch.B., Duncryne, Forres, to Elizabeth Ross, S.R.N., S.C.M., Ivy Cottage, Forres.

Arnott—Burt.—On Feb. 21, 1948, in London, David Charles Arnott, M.B., B.S., D.C.H., to Ruth Margaret Burt, M.R.C.S., L.R.C.P.

Pezeshki—Jones.—On March 20, 1948, S. H. K. Pezeshki, M.R.C.S., of Persian Embassy, to Audrey Elizabeth Jones, S.R.N., of Slindon, Sussex.

DEATHS

Hay.—On March 12, 1948, at University College Hospital, London, Malcolm Bell Hay, M.R.C.S., L.R.C.P., D.P.H., aged 71, late West African Medical Service.

Heywood.—On March 10, 1948, at Earncliffe, Alderley Edge, near Manchester, Charles Christopher Heywood, M.B., B.Ch., M.R.C.P., aged 82.

Laird.—Recently, at 5, Neville Road, Rathgar, Dublin, Harry Seymour Laird, L.R.C.P.&S.I., and L.M., aged 77.

MacMillan.—On March 11, 1948, at Perth Royal Infirmary, Evan MacMillan, M.B., Ch.B. Ed.

Newbigging.—On March 8, 1948, at Holmfild, Lanark, Thomas Duncan Newbigging, M.B., C.M.

Oliver.—On March 6, 1948, at Malvern House, Marshfield, Richard Harris Oliver, F.R.C.S.I.

Pearce.—On March 5, 1948, at Rest Harrow, Uplyme, Lyme Regis, Athol Stewart Joseph Pearce, M.B., B.Ch.

Prentice.—On Feb. 29, 1948, at Lusaka, Northern Rhodesia, George Prentice, L.R.C.P.&S. Ed., L.R.F.P.S. Glas.

Reid.—On March 10, 1948, at 53, Alnwickhill Road, Edinburgh, Edward Waymouth Reid, Sc.D., LL.D., M.B., F.R.S., late Professor of Physiology, University College, Dundee, St. Andrews University, aged 85.

Robertson.—On March 6, 1948, at Bridgefoot House, Thornton-le-Dale, Pickering, Yorks, Douglas Robertson, M.B., Ch.B., aged 49.

Stollerforth.—On March 6, 1948, at Heather Cottage, Burchclere, Newbury, Btks, Charles Sigismund Stollerforth, M.R.C.S., L.R.C.P.

Turle.—On March 6, 1948, at Duffield House, Bexhill, James Evan Turle, M.R.C.S., L.R.C.P., aged 70.

Young.—On March 12, 1948, at Glasgow, Roy Frew Young, M.C., LL.D., M.B., B.Ch., F.R.F.P.S. Glas., of 2, Park Quadrant, Glasgow.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Iron in Anaemia

Q.—*Are the various proprietary tablets of ferrous sulphate, manganese, etc., as effective as a mixture containing large doses of iron and ammonium citrate for the simple anaemia of women? Is the action of the iron reinforced by giving dilute hydrochloric acid before meals and a maintenance dose of vitamin C daily?*

A.—The only drug required in hypochromic anaemia is iron. There is no clinical justification for adding manganese or other substances, although some experimental work has suggested that the effect of iron may be enhanced in this manner. These experiments refer to animals, and there is no evidence that their results are applicable to man. Pills of ferrous sulphate are quite as effective as mixtures of iron ammonium citrate—9 gr. (0.585 g.) daily of the former is therapeutically equivalent to 90 gr. (5.85 g.) daily of the latter. Only ferrous iron is absorbed from the alimentary tract, and in the patient with achlorhydria conversion to the therapeutically inactive ferric ion takes place rapidly. It is possible that dilute hydrochloric acid may have some effect in preventing this, and thus in facilitating absorption; nevertheless there is little clinical evidence in support of this suggestion. Ascorbic acid may be valuable in this respect, by virtue of its reducing action: it has been shown that large doses of ascorbic acid (300–500 mg.) given at the same time as iron will lead to repair of anaemia in some instances where iron alone was ineffective. This seems to be due to maintenance of the ferrous state by the vitamin's reducing action, and can be duplicated with other reducing agents.

Quinine in Early Pregnancy

Q.—*Is there any evidence that quinine taken for the purpose of inducing abortion at about two months of pregnancy has a deleterious effect on the subsequent mental development of the child?*

A.—Quinine traverses the placenta in small amounts in late pregnancy, so early chorion may also be pervious to it. Although it is believed that large doses sometimes cause death of the foetus in late pregnancy or damage its auditory nerve, such possibilities have never been fully proved. There are reports of experimental work on birds and fish which go to show that quinine poisoning affects unfertilized ova and delays the development of fertilized ova, but it has not been demonstrated that the early human foetus is influenced when quinine is administered to the mother, at least not when therapeutic doses are used. Perhaps the best evidence is to be obtained from countries in which malaria is common and in which women in the early months of pregnancy often take even large doses of quinine to prevent or cure the disease. Most observers are agreed that this treatment has no significant ill effect on the children of such women. Even when abortion has occurred it would appear to be more often due to the malaria than to its treatment.

Sterilization of Eye Instruments

Q.—*Is the electric hot-air sterilizer suitable for the sterilization of eye instruments? If so, what temperatures and times are recommended? Does this method impair the delicate points and cutting edges of knives, needles, and the like?*

A.—The electric hot-air sterilizer is extensively used in French, German, and Scandinavian eye clinics, and can be recommended for the sterilization of eye instruments provided that: (a) they are conventionally cleaned before insertion; (b) they have no component liable to damage by heat—this debars cataract knives with ivory handles, irrigators with rubber tubing, diathermy electrodes insulated by rubber or varnish, and "Record" syringes in which the cement between metal and glass may be affected; (c) the sharp instruments are

"racked" in a container which protects them from damage and contamination during stowage, removal, and storage; and (d) the temperature is adequately controlled by a thermostat and a thermometer or chemical temperature indicator close to or among the instruments during sterilization.

The temperature and time required for sterilization are interdependent, and various views have been expressed. Marchesani (Hamburg) claims that five minutes at 180° C. is adequate to kill all spores without corroding cataract knife blades. His special sterilizer with a built-in fan can pass from 15° to 180° C. and back in six minutes, making a total sterilizing time of eleven minutes. Moritz, on the other hand, aiming at a similar temperature in a sterilizer of older design, found a yellow tarnish on knife blades after five minutes. This suggests that the temperature (which varied by 30° C. in different parts of the oven) must in one portion have exceeded 200° C.—the critical temperature for steel. The converse has been recorded by Hanne, who found many hot-air sterilizers in Berlin ineffective, as portions of them remained below the sterilizing temperature. Holth advises 30 minutes at 160° C., which he claims does not affect the strength of silk sutures. His sterilizer takes several hours to reach a steady temperature before insertion of the instruments.

With the majority of ovens at present in use in Great Britain the standards recommended are those of the M.R.C. War Memo. (1945, No. 15) on the sterilization of hypodermic needles and all-glass syringes by hot air, which advises one hour at 160° C. This may take more than two hours in all, so that three cataract operations on the same morning will (unless the blunt instruments used are sterilized by boiling) require the previous sterilization of three complete sets of instruments. On the other hand, even repeated sterilization by this method leaves the edges and points of the finest instruments clinically and photomicrographically unimpaired—a great advantage in ophthalmic surgery.

Prolapsed Cervical Disk

Q.—*What are the symptoms, signs, and diagnostic criteria of a prolapsed cervical disk? How should it be treated? Is the prognosis good?*

A.—The clinical picture in cases of prolapsed cervical intervertebral disk is variable and depends not only upon the level of the disk affected but also upon the situation of the prolapse in relation to the midline. Thus where the prolapse occurs in or near the midline the spinal cord itself may be compressed, with symptoms of an upper motor neurone lesion below the level of the compression. On the other hand, when the prolapse is laterally placed, pressure may be exerted on a cervical nerve root, with symptoms related mainly to the distribution of the affected nerve. The nerve root compressed is always numerically the one immediately below the affected disk—e.g., prolapse of the fifth disk will compress the sixth nerve root, and prolapse of the sixth disk will compress the seventh nerve root. In practice it is found that a large proportion of the cases fall into two reasonably well-defined clinical groups, corresponding to lesions of the fifth and sixth cervical disks. Often, however, the clinical picture is ill defined and even vague.

Symptoms.—In a typical case the symptoms are related partly to the neck and partly to the arm. There may be a history of trauma—for instance, an awkward twisting movement of the neck. Pain is felt locally to one or other side of the spinous processes, and neck movements are painful and restricted. After an interval of hours or days the pain is felt to radiate downwards to the shoulder and arm. If the sixth nerve root is the one affected the radiation is down the outer border of the arm and forearm towards the dorsum of the thumb. In the case of the seventh nerve root the radiation is over the outer aspect of the shoulder and the posterior axillary fold, down the postero-lateral aspect of the arm and forearm to the wrist, sometimes extending to the index and middle fingers. The pain is not necessarily severe and may be more in the nature of uncomfortable paraesthesiae.

Signs.—In the cervical spine there is some degree of limitation of movement by pain, usually most pronounced on lateral flexion towards the affected side and on backward extension. Downward pressure on the head may cause pain radiating down

the arm. Head suspension, on the other hand, tends to relieve the pain. In the arm the signs depend upon the root affected. In the case of the sixth cervical root there may be weakness of the biceps muscle and diminution of the biceps-jerk. In the case of the seventh cervical root there may be weakness of the triceps and wrist extensors, with diminution of the triceps-jerk. There may be some blunting of sensation, but not complete anaesthesia, in the distribution of the affected root.

Diagnosis.—This is based on a careful consideration of the history and findings, and may be supported by radiological changes in the form of narrowing of one or other of the cervical disk spaces. Radiological examination also helps to exclude other causes of root symptoms. In occasional cases it may be desirable to seek more accurate information by means of contrast myelography. Somewhat similar symptoms may be produced by pressure on the cervical nerves after their exit from the bony column—e.g., by a cervical rib. Differential diagnosis is not always easy.

Treatment.—Initially, conservative measures should be tried. Minor degrees are often helped by physiotherapy. Occasionally a judicious manipulation of the cervical spine is useful and there is little risk of increasing the amount of prolapse if flexion movement is avoided. None the less, the risk should always be borne in mind when considering the advisability of manipulation, particularly under anaesthesia. Severer cases can be relieved by rest in bed, with traction of 5–10 lb. (2.27–4.54 kg.) applied via a halter. Within 10 to 14 days relief is sufficient to allow the patient to get up, but it is wise to apply a collar of moulded leather or plaster-of-Paris for the next six to eight weeks. It is rarely necessary to include the arm in the plaster. Only when the symptoms are severe and persistent or when disabling attacks occur should operative treatment be considered.

Prognosis is on the whole good. The great majority of cases clear up spontaneously within six to 12 weeks. Persistent or recurrent cases have been satisfactorily treated by operation.

(See also an annotation on this subject in the *Journal* of March 13 at p. 505 and the report of a discussion in our issue of March 20 at p. 557.)

Estimation of Bile Acids

Q.—Is there any reliable test for estimating bile acids in the plasma or serum?

A.—Several methods have been described, but the variation in their "normal range" suggests that they do not measure true bile-acid concentration. The most satisfactory appears to be that of Josephson (*Biochem. J.*, 1935, 29, 1519), which was recently used by Sherlock and Walshe (*Clin. Sci.*, 1948, 6, 223) in a thorough survey. The normal range is 0.2–3 mg. per 100 ml., and rises in obstructive jaundice to as high as 6.6 mg. per 100 ml. (as cholic acid), but the overlap between normal persons, patients with infective hepatitis, and patients with obstructive jaundice is so great that the results of the test are of no clinical value in the differential diagnosis of liver disease.

Penicillin Blood Levels

Q.—In a moderately severe infection, with or without pyrexia, such as tonsillitis, furunculosis, or septic wounds, from which an organism as penicillin-sensitive as the Oxford staphylococcus has been cultured in the laboratory, what level of penicillin in the blood should be maintained, and for how long? The blood level is of course high immediately after parenteral administration, depending on the dose given. Does it necessarily follow that the raising of the blood level will shorten the duration of the infection, or must one be guided by the patient's condition before stopping penicillin?

A.—The minimum concentration inhibiting the growth of such an organism is about 0.02 unit per ml. If this is continuously maintained or exceeded in the blood, it will also be maintained in the infected area of tissue. If adequate doses are given at reasonably short intervals, even though the blood level falls below this minimum before another dose is due, diffusion into the tissues while the level is high will ensure that local effect is maintained. How efficient this mechanism is must depend on the rate of exudation into the inflamed area and other factors. There is *in-vitro* evidence that somewhat higher concentrations are more rapidly bactericidal, but the

range to which this statement applies is small, and above this no increase in concentration has any enhanced effect. There can be no arbitrary rules about the duration of treatment; the indications for stopping it are clinical signs or laboratory evidence that the infection has been overcome.

NOTES AND COMMENTS

Archives of Disease in Childhood.—The Editor of the *Medical Journal of Australia*, Dr. Mervyn Archdall, wishes to obtain copies of the March and June, 1944, issues of the *Archives of Disease in Childhood*, which are now out of print. Dr. Archdall's address is Seamer Street, Glebe, New South Wales, Australia.

Treatment of Chilblains.—Dr. W. H. McKINSTRY (Rottingdean, Sussex) writes: Dr. R. John Gourlay (Feb. 21, p. 336) has discovered that nicotinic acid will cure chilblains. When I was in practice about 1896 I cured chilblains by giving cod-liver oil. This remedy was given by me as I found my patients taking cod-liver oil for other diseases, as phthisis, did not suffer from chilblains. Nicotinic acid at that time was unknown.

Vitamin B and Growth of Hair.—Dr. AGNES SAVILL (London, W.) writes: The subject of the effect of *p*-aminobenzoic acid on hair, especially on greying hair, was investigated by Benjamin Sieve and several other American writers many years ago. Sieve published the results on 460 patients in 1941. The drug became unobtainable during the war, as it was required for other purposes. Doubtless this explains why this research has been forgotten. In the third edition of *The Hair and Scalp* I have given references to all that I could trace on the subject. The reprint has taken over two years to appear, owing to the acute paper shortage from which all medical publishers have suffered.

Piercing the Ears.—Dr. H. MAITLAND MOIR (Currie, Midlothian) writes: The ring presented by the patient has a locking device. It is impossible to lead the one half of the ring through a straight piercing. After piercing the ear with a straight skin-needle, the two ends of the ring are placed in the "pierce," i.e., one behind and the other in front; then they are forced together and lock in the tissues. Before learning this trick I used to use a silk suture, which was effective if unsightly.

Cataract.—"Partial Eclipse" writes: Perhaps your inquirer on cataract ("Any Questions?" March 13, p. 531) may be interested in my own case. My left eye was operated on four years ago for cataract. Vision, when corrected with a strong lens, is 6/5 in that eye. Vision in right eye is P.L. only, owing to a mature cataract in that eye. I can read for hours without strain. The main drawbacks are: (1) The peripheral field is severely restricted. (2) Inability to judge distance. An object 9 feet distant appears to be only 6 feet away. (3) Objects are considerably magnified.

Some of the consequences of these drawbacks are more commonly felt out of doors. Movement on a pavement is generally punctuated by bumps on the right side from pedestrians who approach from my blind side. To cross a road carrying only light traffic I must wait at a crossing and then cross with the crowd. I can and do ride a push-cycle on quiet roads. When making a turn to the right I can sometimes manage to look over my left shoulder far enough to see traffic approaching from the rear, but I find it generally safer to dismount. I was desirous of taking up motor-cycling again, but decided that the risk was too great. It would be impossible for me now to drive a motor-car with safety anywhere outside the Sahara Desert, though before the onset of my cataract I had driven for many years.

A one-eyed man with a lens in his eye has many advantages over the individual who has to carry his lens on his nose.

Correction.—In the annotation under the heading of "Thirty-million Volt X Rays," published in the *Journal* of March 20 we referred to developments in the nuclear physics laboratories of the General Electric Company at Stafford. This was an error, and the reference should have been to the English Electric Company.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY MARCH 27 1948

British Medical Association SPECIAL REPRESENTATIVE MEETING

DEMAND FOR CHANGES IN THE ACT

UNANIMOUS DECISIONS

The Special Representative Meeting summoned to consider the result of the plebiscite and certain recommendations of Council concerning the National Health Service Act and acceptance of service was held in the Great Hall of B.M.A. House, London, on Wednesday, March 17. About 350 representatives were in attendance from all Branches and Divisions of Great Britain. Dr. J. B. Miller, of Bishopbriggs, presided. He was supported by Dr. H. Guy Dain, the Chairman of Council, Sir Hugh Lett, Bt., President, Dr. J. W. Bone, Treasurer, and other officers of the Association. The agenda contained 170 motions and amendments, but the whole of it was covered in a meeting which lasted, with two short intervals, for 8½ hours. Except for a short private session, the meeting was open to the Press and to strangers.

Tribute to Council and Headquarters Staff

Mr. Douglas S. Pracy (Nuneaton and Tamworth), before the meeting proceeded to its main business, moved to place on record the gratitude of the profession to Dr. Dain and the other members of the Council for their untiring efforts, especially during the last three months, in addressing meetings of Divisions and otherwise making known the important matters at stake; also to Dr. Hill and the Headquarters staff for the efficient manner in which they had carried out the duties falling to them and especially in the difficult task of keeping in touch with members in all branches of the profession.

The motion was carried with prolonged acclamation, which was renewed when Dr. Dain rose to acknowledge the tribute. He said that on behalf of the Council he wished to thank the meeting for the way in which this motion had been received. "We have as your servants endeavoured to put forward the policy you have laid down, and I take it from the terms of this resolution and from the way you have received it that you are satisfied with the manner in which we have advanced the policy for which the Representative Meeting is responsible. I hope that we shall be able to retain that confidence."

A further motion by Salisbury was carried expressing appreciation of the work of the Editor and staff of the *Journal* both in keeping the profession informed of the progress of events and in moulding opinion by means of a valuable series of leading articles.

Dr. O. C. Carter (Chairman of the Journal Committee) said that the Association expected so superlatively high a standard of work from its officers that it was inclined to take too much for granted. They had in their Editor and staff a first-class team, and he knew that their work during the last few months had been welcomed throughout the country. The quality of argument advanced in the *Journal* had played a large part in enabling the members of the profession to come to a decision on how they should vote in the plebiscite.

Representative Character of the Association

Lord Horder (Marylebone) moved:

"That in view of the continued misleading statements made by the Minister of Health and supported by some sections of the Press this Meeting wishes to place on record its opinion that the British Medical Association is thoroughly representative of the medical profession and that the Council and the B.M.A. representatives on the Negotiating Committee could not be elected more fairly or freely."

Lord Horder said that this was in effect a vote of confidence in the Association as being thoroughly representative of the profession. In such a meeting as the present the motion might be redundant, but outside that hall, largely as a result of mendacious statements in the House of Commons and in a section of the Press, doubt had been thrown on the position of the Association as a constitutional democratic body and on whether in fact it represented the profession. It was an example of the unscrupulousness of the Minister that he arranged for a period of some 12 months that his chief secretary, his principal medical officer, and his chief adviser should meet a body appointed in the main by the Association, with an addition from other bodies in the profession, and should then, as a result of two short sessions following that prolonged period, having failed to get what he wanted, say that this body was a small body of spokesmen who had consistently misled the great profession which they were supposed to represent. He had also accused the B.M.A. of being engaged in a "squalid political conspiracy." The same unscrupulousness had been followed by certain of the Minister's colleagues. A gentleman with a "song in his heart," which turned out to be his swan song, copied the line taken by a certain newspaper and spoke of the Negotiating Committee as a handful of elderly doctors dictating to the profession. In the public interest it seemed desirable to nail these lies to the counter. (Applause.)

Perhaps a slight significance, Lord Horder continued, attached to the fact that it was Marylebone which proposed this resolution, because Marylebone had not in the past been averse from offering criticism, he hoped of a constructive kind, and Marylebone was thoroughly appreciative of the fact that the Council had accepted these criticisms in good spirit.

"We believe that the Association has got the confidence of the public in a fuller measure to-day than ever before. This is reflected in the fact that, of 68,350 doctors registered in the British Isles in January of this year, 58,000 are members of the Association. But I would not put the profession's confidence to-day at the height at which I believe it to exist merely on numerical strength. I believe it to be due to the realization that the Association's policy, as crystallized in the well-known principles, to give way on which would be to sell the pass, commands the adherence of the whole profession. The

Association regards the points at issue not as bargaining points but as indicating the desire of the doctor to be a free man—free to practise his science and art in the patient's interests. It is because we feel that the same spirit animates the Council that we are satisfied that the Council adequately represents us.

"I am sometimes accused of being too much a 'B.M.A. man,' but I do not lose my equanimity over that. I am more and more a 'B.M.A. man' because I realize that if we stick together we shall win. In order to stick together we must have a focus point for our power, and that focus point is the B.M.A. There are certain other distinguished bodies within the ambit of medicine, but, whether from their constitution or some other reason, the immediate fight lies not with them.

"Can we possibly lose? Yes, I think we can possibly lose. We can lose by squabbling as to which of these principles is the most important. We can lose by arguing as to which of these principles we should yield to the Minister first or last. That way madness lies. We must not yield on any of the points which collectively or individually sell the doctor's freedom. I have watched the Negotiating Committee cut the joint to the bone. There is nothing left to go, except our freedom, and that we dare not give. Once this position is made abundantly clear to the Government, legislation against the nationalization of medicine is quite certain. We in Marylebone believe that the Association shares this view, and we confidently bring this motion before you." (Loud applause.)

Dr. J. A. Pridham (Chairman of the Organization Committee), reported that the membership of the Association had reached the record height of 58,195, or 75% of the total profession in the United Kingdom. If retired practitioners were eliminated the percentage was 77.5. Between 1935 and 1940 the Association increased by 5,000 members, but from 1940, when the profession became aware of the events impending, to the present date the membership had risen by 19,000.

The motion was carried unanimously.

The Plebiscite

The Chairman of Council (Dr. Dain), in moving that the statement of the results of the plebiscite be received, emphasized the more striking features. It must be apparent to the whole country that there was something seriously wrong with a National Health Service Act which had provoked so strong a demonstration against it as the overall figures of the plebiscite revealed. The Minister had made a definite effort to split the profession into two by offering certain concessions to consultants and specialists; the results must have been disappointing to him, because the consultants and specialists headed the list with the largest percentages of those who regarded the Service with disfavour. They had to thank the consultants for realizing the extent to which these proposals were likely to impair their freedom. It appeared that the whole profession was seriously disturbed. Members who were not concerned in any way with service under the Act, such as whole-time research people, medical personnel in Government service, and in the public health services, all saw that if the Service in its present form came into operation their essential freedoms would be endangered.

Dr. Noy Scott (Plymouth) asked the meeting to express the opinion that the profession should stand by the position as revealed by the plebiscite results. "The fight is now on and the time for action is now."

Dr. Dain said that Plymouth was rather short-circuiting the whole business of the meeting by saying, "Stand by the plebiscite and that is all there is to do." Of course they stood by the results of the plebiscite, but that was not to say how they should implement them.

The Chairman of Council's Statement

Dr. Dain at this point reviewed the situation. He said:

"We had better start with the history which leads to the plebiscite, because we want to have a clear understanding of our position and of the action which should flow from it. In the early part of last year we agreed to go into discussions at the Ministry on the understanding that amendment of the Act was not excluded. But in fact amendment of the Act was excluded, as we found when we came to meet the Minister.

We were satisfied, by the attitude that he adopted, that he had never intended to amend. He knew that, following the discussions, we should take a plebiscite. We did our utmost to place things fairly before the profession as a whole. We gave our report of the discussions and the Minister's reply equal publicity, sending them to every member of the profession. That, however, has not protected us from manœuvres of various kinds. When the plebiscite was arranged the first thing that happened was a suggestion that this was a form of intimidation to be put across to the profession in order to force them, against their will presumably, to stay out of the Service. The Minister made that accusation without the slightest grounds for doing so. When a body like ours gives an undertaking that the secrecy of a document will not be broken it must be assumed that we are honest in such an undertaking. We should take such steps as are necessary to protect ourselves against any imputations to the contrary. (Applause.)

"Then, although the Minister had told us that we were free to come or not to come into the Service, we have been accused of sabotaging an Act of Parliament. The Minister had himself given us the authority to decide whether we should come in or should not come in. Then a charge was made that the plebiscite was not being correctly counted and that secrecy was being given away. Indeed, so far from intimidation on our part, I may say that when we invited the Minister to come and see for himself how it was done we had letters expressing the hope that the Minister would not be allowed to come too close to the papers in order that he might see how any particular practitioner had voted! (Laughter.)

"During the taking of the plebiscite the extraordinary thing happened that a debate was arranged in the House of Commons on an Act which had already become law, the debate taking place on a resolution by the Minister who had been in charge of the Bill. We can take credit for having set up a new precedent in the House of Commons. If you ask me why the House of Commons should have undertaken such an extraordinary proceeding, it is hard to find any other answer than that it was an attempt by the Minister to intimidate us during the course of our voting. In the debate we were accused of being politically inspired, and at the same time we were told that we were awkward people who had not agreed with Ministers of Health to whatever party they might have belonged. What sort of party politics inspires us when we are so awkward with all parties it is not easy to say. But those are the manœuvres which the Minister has improperly used to influence us in our important decision with regard to service under the Act.

"The results of the plebiscite showed that he has completely failed to divide the profession or to influence it in forming its opinion. It is very unfortunate that a problem which is of great national importance should have been approached either with emotion or in a spirit of party politics. We are perfectly competent to devise a service in which it is entirely unnecessary for anybody to become emotional. We want to have regard only to the efficiency of the proposed Service and to exclude it from entirely unnecessary political ideologies.

The Power of the Minister

"What are our objections to the Act? How comes it about that 90% of doctors think it unsatisfactory? The overall considerations are the Minister's powers. It has been said that power corrupts, and absolute power corrupts absolutely. The Minister's power in this Act is absolute. All sections of the profession are opposed to it and we speak for all of them. The Minister claims that we are 'raucous voiced people' speaking without authority. That claim has been completely disproved by the plebiscite and our solidarity has remained more evident than ever. We have not been shaken by threats or abuse. The power of the Minister will lead to the enslavement of the medical profession. We believe that ultimately it will lead to a service in which we shall be completely controlled, in effect, by the officers of the Ministry. We, of course, deal with Ministers, but, assuming that a service of some kind is running, it will be run by the principal officers of the Ministry and it is for them to see that their controls are so good that they will not get into trouble with the Minister himself or have unpleasant questions asked

in the House of Commons. If we enter this service without proper safeguards we shall be landed as servants of the Ministry of Health, whether whole-time salaried or not.

"We set out, as we thought, to establish a health service, and we found to our great disappointment that we were engaged in a life-and-death struggle for our freedom and independence. We never anticipated that that would be the ultimate outcome of the attempt to set up a National Health Service, but we must not disguise it that that is the position. If we do not have this Act amended in appropriate ways before it comes into force we shall have lost our independence and our freedom. It is for us to see, in the interests of the progress of medicine in this country and in other countries, that we do not fail. If you say that the Act does not put us in jeopardy my answer is that 40,000 doctors have said in the plebiscite that they believe that it does so.

"We are not concerned at this moment with financial considerations. There has been no proper opportunity of discussing remuneration for consultants or general practitioners or any other branch of the profession. The monetary question is not one which has influenced us in our decision. Unscrupulous propaganda has been put out that this is a stunt of the doctors to make more money. We can completely refute the statement that in the action we have taken we are influenced by financial or monetary considerations in any way.

"This Act is a paper service and nothing more. (Applause.) The people who have been promised a free-for-all service available to everybody are going to be very greatly disappointed. The Service will not and cannot be there on July 5 or on any reasonably approximate date. A wise Government would have thought it the proper way to start such a service by stages. I hope we shall not lend ourselves to any idea that the Service can properly be implemented by the given date. The failure of the Service must recoil on the people who produced it well knowing that it was impossible to implement it. (Applause.) The temptation to try to get the medical profession into the grip of a Government Department has been too much for them. The Government is starting an insurance service on July 5 and it wants certifying doctors firmly in its grip before certificates are required to be issued.

"All our points of objection are based only on one thing, our determination that when we take part in a service we shall not risk our freedom and independence and shall act always in the interests of the patients who have placed their confidence in us." (Loud applause.)

Ready to Enter into Discussions

In conclusion Dr. Dain said:

"We are accused of intransigence. Yet our position to-day is that we are willing to explore the problems afresh provided that the outcome is a service in which the medical profession remains an independent profession secure from domination by the State. Can I say more?

"We doctors want a health service. We want our services to be available to all who need them. We are ready to enter into any discussions directed to making it possible for the medical profession to co-operate with the Government. If the Government can show us other ways, new ways, of preserving our independence, we are willing to listen. But if this cannot be done, we owe it to the public to make our stand.

"We ourselves approach the prospect of a fight in anything but a light-hearted mood. Whatever may be said on the other side—and it has been often rumoured that some political circles are not unwilling, as they put it, to 'smash the doctors' as the first step to reducing all independent workers to subservience—we ourselves can have no place for any such irresponsible levity. We know there is too much at stake in this fight—for ourselves, for medicine, and for the public as a whole. But prepared as we are for discussions aimed at conserving our essential freedom, willing as we are to examine new proposals, I should be failing in my duty to the profession and to the public if I did not make absolutely clear that in the absence of such necessary changes we shall stand as a united profession outside this Service, continuing with our daily work, but unwilling to enter a service which in its present form is inconsistent with the freedom of medicine and of the public." (Loud continued applause.)

The Council's Recommendation

The Chairman of Council then moved, on behalf of the Council, the following recommendation:

That the Representative Body, reaffirming the whole-hearted desire of the medical profession for a comprehensive health service available to everyone, urges that in the public interest such changes should be made in the National Health Service Acts of 1946 and 1947 as are necessary to maintain the integrity of Medicine and to prevent doctors being turned into State servants, with harmful consequences to patient and doctor alike. The Representative Body, therefore expresses the hope that the Government will make it possible for the profession to co-operate by making such changes, and states its view that it is not in the best interests of the public or of Medicine for members of the profession to enter the Service until such changes are made.

Dr. Dain said that this resolution had been framed carefully and it expressed exactly what they needed to say. There were many resolutions on the agenda seeking to modify it in one way or another. There were resolutions which suggested that it was too mild. His reply to that was that one did not show one's courage or determination by the force of one's words. They were a reasonable body of people determined if possible to get a service established in which they could co-operate. He hoped the meeting would not spend a great deal of its useful time that day in altering the words of the motion.

Dr. H. A. Summers (Nottingham) moved a substituted wording for the Council's recommendation. He said that the sense was the same, but the Nottingham phraseology, he thought, was more clear and simple.

Dr. W. Gunn (Greenwich and Deptford) also thought that the wording was not direct enough.

Dr. E. A. Gregg said that the Panel Conference on the previous day had spent some time considering similar amendments and had come to the conclusion that the original resolution was quite good enough to express their views.

The Nottingham substitution found no support and was lost.

Dr. D. L. Little (Dudley) moved that the following be substituted:

The Representative Body, confirmed in its judgment by a plebiscite of doctors most carefully and honestly carried out, declares the National Health Act, unamended, to be contrary to the public weal and the traditions of the profession. The Representative Body therefore calls on the medical profession to reject the Act and to continue to serve the public by independent practice, making suitable provision for everyone in this Island.

He said that in Dudley they felt strongly that the Minister had no intention now, nor had a year ago, of amending the Act, and if they went on hoping that the Government would change its attitude in the matter they were really playing into the Government's hands.

Dr. Dain said that he hoped the meeting would not accept this amendment. It was an attempt to mix policy with action. The Council's resolution was concerned with policy; they would have to consider action later in the day.

Dr. G. O. Barber (Mid-Essex) commended to the movers of this and other amendments that they should implement the vote of confidence they had already passed in the Council by withdrawing their amendments.

It was agreed to pass to the next business, and the original recommendation of Council as moved by Dr. Dain was then put to the meeting and carried unanimously.

Conditions of Any Future Settlement

The first of 40 motions on this subject was by Mr. Tudor Thomas (Cardiff), who moved:

That ownership of goodwill by the practitioner, abolition of basic salary and of powers of direction, and the right of appeal to the courts be regarded as essentials in any settlement with the Minister.

Each of these individually was important, but there was a close relation between them. It was desirable that they should be emphasized collectively rather than separately. It was not an exclusive list, but contained the essentials to guarantee their freedom.

Dr. E. W. Goodwin (Leicester and Rutland) said that if the results of the plebiscite meant anything at all they meant that every section of the profession was voicing its deep protest

against the attempt of the Minister to deprive the individual practitioner of a large measure of his independence and freedom. The safeguards of freedom were these four well-known principles. Dr. D. V. M. Adams (Lanarkshire) declared that the continued right to buy and sell practices and to be paid only by capitation were vital to the freedom and security of the profession.

Dr. Dain said that on many occasions the Representative Body had expressed with great forcefulness its determination that certain principles should be maintained. The time of the present meeting was not being spent profitably in saying the same thing over again. More than that, they might be driven into the undesirable position of establishing a list of priorities in their demands. If the Government came along with new proposals they were prepared to examine them, on one basis, that they provided for the freedom for which the present Act did not provide. He hoped they would not go on reiterating their opinions on the importance of these things, because in doing so they lost sight of the one thing that was essential—namely, their objection to the vast powers which the Act placed in the hands of the Minister. He begged them not to enter into a Dutch auction or a bargain sale, but to keep in mind the maintenance of freedom and independence. (Applause.)

The Chairman said that that was a statesmanlike appeal, but as chairman he must maintain the rights of Divisions and allow motions which appeared on the agenda to be moved, or, if they were covered by other motions, give the representative an opportunity to speak.

Dr. A. H. Forman (Fife) said that his Division felt that the Council should adopt a more vigorous, constructive, and fighting policy. Dr. A. G. Manley (Richmond) said that he wanted to take the opportunity, in view of the public speeches of a former representative of Richmond (Dr. Stark Murray), of saying that in that Division, save for a very small minority, they were wholeheartedly behind Headquarters policy. Dr. D. C. Barron (Sheffield) said that his Division wanted the meeting to reaffirm its opinion that the continued ownership of practices was an essential factor in maintaining the freedom of the doctor, upon which depended the rights and privileges of the patient. If the profession accepted compensation for the abolition of goodwill it would be "buying" control.

Dr. C. K. Cullen (City of London) moved an amendment instructing the Council to seek the abolition of the Minister's power to convert the profession to a full-time salaried service, the amendment adding:

This meeting does not consider the buying and selling of practices, negative direction of doctors, and appeal to the courts as essential factors in the solution of the deadlock.

Their basic fear was of a whole-time salaried service. If they could get a guarantee from the Government that such whole-time salaried service was not in the offing, these other questions were not really essential. The main point was that the Minister had power by regulation to alter certain features of the Act, and the Council should take that as their main ground of opposition in any further negotiation.

Dr. J. A. Gorsky (Westminster and Holborn) said that a serious misrepresentation in the Press which had troubled many doctors was a statement that the B.M.A. was in favour of the abolition of the right to buy and sell practices. Those who made this statement quoted the draft interim report of the Medical Planning Commission published in 1942. That, however, was a guarded statement, and was governed by certain words in italics:

The suggestions contained in the present report should not, therefore, be regarded as expressing the Commission's conclusions but as recommendations made to it which the Commission as a whole has not yet considered and will not consider until the profession has made known its views through the usual channels.

The question relating to buying and selling of practices was merely put down as a question for decision.

Dr. Dain took up the City of London amendment. He hoped the meeting would not attempt to set up priorities either in what it was ready to discard or in what must be retained. He asked that the City amendment be turned down.

The City amendment was put to the meeting and decisively rejected, and the debate continued, with the Cardiff motion as the peg.

Mr. H. H. Langston (Winchester) said that the primary issue was the possible conversion of members of the profession into full-time

salaried servants of the State. Dr. D. T. McDonald (North Northumberland), from a Division consisting almost entirely of general practitioners in rural and semi-rural practice, said that his constituents also held that view.

The Question of Goodwill

Dr. R. W. Cockshut (Council) protested against the picking out of the question of buying and selling practices and making it stand alone. If the Minister were left with his present powers, the retention of buying and selling might not be of any particular use. What would be the value of the right to sell a practice in a closed area or in an area where, owing to shortage of doctors, anyone could get a practice? There was the last body in the world which should deal with symptoms rather than with causes. So far the B.M.A. had played its part with great finesse, and had not made a single mistake. Things that could have gone wrong for them had gone right. He hoped that they would continue to be guided by Dr. Dain in his insistence that the power of the Minister was the primary objection, and the primary requisite was that the profession should be free. In any profession administered by the Minister they could never have any certain guarantee of total freedom.

Dr. J. C. Arthur (Gateshead) said that if at this stage they endeavoured to assess one principle as of more importance than another they would affect the morale of their people. On the practical side it would be foolish to tell their opponents which position they intended to hold strongly and which not to hold at all.

Dr. Dain said that the debate had been confused. He suggested that they got rid of the whole matter by passing to the next business.

It was agreed accordingly to proceed to the next business, which meant that no vote was taken on the Cardiff motion.

Dr. Arthur then moved to reaffirm adherence to the principle that no penalty should attach to doctor or patient who elected to remain outside the Service. Incidentally he referred to a letter by Sir Henry Morris Jones, M.P., in *The Times* of that morning which supported the suggestion made by a correspondent of that paper that many of the powers now conferred on the Minister could with advantage be transferred to a Central Medical Practices Committee; in particular the method of payment could be handed over to that committee, and payment by attendance, which had worked well in France, should not be excluded.

Mr. C. E. Beare (Reigate) said that the principle of no penalty for remaining outside the Service had been endorsed over and over again. It was on the understanding that that principle would be safeguarded that they gave up their point on the 100% issue. Dr. J. A. Ireland (Council) said that "no victimization" was a principle of organized labour and he thought it should be the principle of the profession also.

Dr. O. C. Carter (Council) said that they were wasting time in trying to safeguard interests in one respect or another. The importance of that day's meeting did not lie in the motions so much as in the statement made by the Chairman of Council. It was the freedom of the profession that concerned them. Once in history the great contest was over the divine right of kings. The situation had now changed and "we are faced with the divine right of a Cabinet Minister to play hell with the medical profession and the health of the country."

The Gateshead motion reaffirming adherence to the principle that no penalty should attach to either doctor or patient who elected to remain outside the Service was carried, as was also a motion by South-West Essex urging that, in the event of negotiations being resumed, neither consultants nor general practitioners should agree to terms until both sections of the profession were mutually satisfied with them. The mover, Dr. E. R. Tivy, said that the Minister had made an attempt to divide consultants from general practitioners, but the consultants had rallied gallantly to the support of their general practitioner colleagues, and no division of the profession must be allowed to occur again.

Question of Reopening Negotiations

Dr. G. W. Ireland (Lothians) moved a resolution expressing willingness to reopen negotiations with the Government, and that if there was such reopening, concessions might be made provided that an amending Act was passed to ensure that a whole-time salaried service would not be introduced. This motion was not inspired by fear or indecision. His Division was as loyal to the B.M.A. as any in the country. Both sides were strong enough to stand firm against each other. The present situation, if unrelieved, would only lead to bandying of words, exchange of threats, and abuse. Moderate people wanted to see a satisfactory solution of their outstanding difficulties. The only hope lay in one side or the other taking the first step. Was there not some case for a compromise, and

was it not in keeping with the ideals of the profession that they should take the first step? "We have had fine leadership up to now; let us now have statesmanship. As Smuts has said, quarrels are dangerous tactics. This is not peace at any price. If you offer concessions and the Government remains adamant, public opinion will swing right round in your favour. It is rare in these days to see the spirit of magnanimity, but it is most rewarding."

Dr. Helme (Guildford) considered this to be "one of the most frightful expositions of appeasement" he had ever heard.

Dr. D. S. Robertson (Edinburgh), while agreeing with a part of the motion, thought the word "reopen" an unfortunate one. It was very important that a clear expression of opinion should go out from that meeting that they were prepared to take part in further negotiations if and when these were opened. He said this because of the repercussions on public opinion. He did not advocate defeatism; but he thought they should indicate their willingness to take part in fresh negotiations and so rally public opinion to their side.

Dr. Dain hoped the meeting would not have anything to do with the resolution. He repeated what he had said in his speech in opening the debate concerning their readiness to enter into discussions. Could it be said more clearly, definitely, or firmly? He hoped it would be left at that.

The Lothians motion was lost, hardly a hand being lifted in its favour, and the same fate befell other motions by North Northumberland and Winchester suggesting certain provisions which should be made in an amending Act. A motion by the Isle of Wight (Dr. Howie Wood) was accepted, advising the profession against participating in the new Service unless guaranteed that no material changes in the terms of service (when finally agreed with the profession) would be made without prior consultation and agreement with the profession.

The Independence Fund

At this point the Representative Meeting went into committee, under the chairmanship of Dr. E. A. Gregg, and afterwards it was announced that it had passed unanimously a resolution moved by Dr. Dain establishing an Independence Fund to help to finance the profession's activities during the present dispute with the Government. The following had been invited to serve as trustees of the new Fund:

Mr. Lawrence Abel, Dr. J. C. Arthur, Dr. J. A. Brown, Dr. G. F. Buchan, Dr. R. W. Cockshut, Dr. H. Guy Dain, Dr. W. E. Dorman, Mr. A. Staveley Gough, Dr. F. Gray, Dr. Charles Hill, Lord Horder, Dr. J. A. Pridham, Prof. G. I. Strachan, Dr. S. Wand, Sir Reginald Watson-Jones, Dr. J. B. Miller, Dr. E. A. Gregg, Dr. W. M. Knox, Dr. J. C. Pearce, Dr. W. D. Steel, Dr. D. J. B. Wilson, and Dr. W. Woolley.

The Compensation Issue

Dr. A. C. E. Breach (Bromley), taking up the point that an attempt is being made to coerce practitioners into joining the Service by the threat of forfeiture of right to compensation unless they join by July 5 next, moved that as a condition prior to any further negotiation the period during which a practitioner might join the Service with full right to compensation should be extended to July 5, 1949. He mentioned the difficulties of the younger men not firmly established in their practices.

Mr. C. E. Beare (Reigate) said that to talk about compensation at all might be implied as signifying willingness to give up goodwill.

Dr. J. A. Gorsky (Westminster and Holborn) said that many of the young members of the profession were under the impression that they were fully entitled to compensation if they went into the Service. That illusion would be dispelled by a study of Sect. 36 of the Act, where it was laid down that the practitioner must show loss by reason of his inability to sell the goodwill of his practice "by virtue of the last foregoing section"—and this was Sect. 35, prohibition of sale of practices, containing the penal clause which they opposed entirely. It was difficult to understand how a practitioner was expected to prove loss when in fact that loss had not yet occurred and might not occur until such time as the compensation was computed. The Minister might refute any suggestion that a loss had been suffered. He commended a study of Sect. 36 (3) (a) as illustrating the Minister's abnormal and inordinate power under regulations. Those younger practitioners who thought they were going to get compensation and were fully entitled to it were labouring under an illusion.

Dr. Laurie Smith (Blackpool) said that to accept the Bromley motion would imply consent to abolition of goodwill.

Dr. Breach said that he was sorry if the wording conveyed that idea. His point had been that the Ministry was here using a big stick with which to coerce the profession, and it was for them to insist that it be laid aside before they entered on any further discussion.

The Bromley motion was lost.

Political Pressure upon Doctors

Dr. J. A. Brown (Birmingham) moved as a matter of urgency the following resolution:

That this meeting condemns as grossly improper the bringing to bear of pressure for political purposes upon individual doctors to induce them to inform outside bodies of their intentions in relation to the new Service.

In support of this motion he read two letters received by doctors in different parts of the country—Cambridgeshire and South Wales. The Cambridgeshire letter, dated March 10, was signed by the chairman and secretary of the local Labour Party and the chairman and secretary of the local branch of the Transport and General Workers Union, and read as follows:

"The attitude of the medical profession towards the new Act which comes into operation in July next is causing considerable anxiety to our combined membership. It will be appreciated that with the advent of the new health service our members are anxious to ensure that they and their families receive the medical advice and assistance to which they will then be entitled. We have therefore been requested to ask you whether or not you propose to participate in the new Service. Should your decision be a negative one we think it only fair that we should know this in order that we should be in a position to take such steps as may be open to us for the protection of our members."

The other letter, dated March 12, was signed by an official of a local branch of the National Union of Railwaymen in South Wales:

"I have been instructed by our members residing in . . . area, at our branch meeting on March 7, 1948, to inquire as to your views regarding the National Health Act to be operated from July 5. They wish to know if you are prepared to operate it on and from July 5. Thanking you for an early reply," etc.

Dr. Brown pointed out that up to the present moment the regulations of the Service had not been published. No official invitation had been issued to any doctor to join the Service. The legal committee to examine the partnership question had not even been appointed. These two districts, Cambridgeshire and South Wales, were so far apart that there could be only one conclusion—namely, that there was some central thought behind these communications. What looked like organized political and trade-union pressure was beginning to be brought to bear on individual doctors.

Dr. Brown said the Association was accused of attempting to intimidate doctors in connexion with the plebiscite, but here was an attempt—and a scandalous attempt—to intimidate doctors by local political and trade-union pressure. No doubt the Association would advise individual practitioners how to respond to such pressure, but it was the duty of the Representative Meeting here and now to condemn this disgraceful attempt at intimidation. (Applause.)

Dr. Brown was handed another communication, this time from the Letchworth Trades Council, which stated:

"At a recent meeting it was unanimously agreed that we should endeavour to ascertain the number of practitioners locally who intend practising under the new Act."

and it was added that concern was expressed regarding the medical service of 3,000 families of trade unionists after July 5. The communication concluded:

"Let us know your intentions so that a general idea of what the situation is going to be like here may be obtained."

No doubt other examples could be brought forward.

The motion was carried.

The Question of a New Approach

Dr. R. H. Bailey (West Middlesex) moved to instruct the Council to take no steps to reopen negotiations with the Minister or his department before July 5. He strongly urged that after the experience of last year they should not be induced

to enter discussions again until their just claims were guaranteed by someone who could speak with authority for the Government.

Dr. S. F. L. Dahne (Reading) said that all that the motion intended was that the profession should not make the first move. If the Minister saw fit to approach them, yes, by all means start negotiations. It would be a despicable sign of weakness to start approaching the Minister now.

Mr. C. E. Beare (Reigate) spoke in the same vein. The Council's resolution had not slammed the door, but it was not for them to make the first move.

Dr. Dain said that he had already stated that they were reasonable people ready to consider any possibility for securing a service consonant with the independence of Medicine. If the motion meant that they should approach the Minister to learn whether he would agree to further discussions, he would be entirely opposed to any such step, but did not want to go out of his way to be rude about it, and he saw no reason why the meeting, having expressed itself as it had done that morning, should pass this resolution, which really did not strengthen the position at all and might only aggravate the situation.

It was moved and agreed to pass to the next business.

Dr. F. E. Gould (Birmingham) moved:

That the Negotiating Committee should approach the Prime Minister forthwith with a view to reopening negotiations.

Everything they had been told confirmed their determination to have nothing to do with this Act until it had been amended. The Association had the support of the profession, but what was it going to do with that support? A good general did not allow his forces to sit down in front of a fortress and waste their time. He believed the action should be a direct approach to the Prime Minister.

Dr. Howie Wood (Isle of Wight), in supporting the motion, said that it was not part of his business to make a personal attack on the Minister of Health, but the events of recent months had shown that he was not a man with whom they could successfully conduct negotiations. The onus of providing a solution should be placed upon the Government. The Prime Minister should be approached directly and asked to make such arrangements as were necessary to allow amicable and successful conversations to be started.

Dr. D. G. Morgan (Kingston-on-Thames) said that it was evident that the profession had lost confidence in the present Minister, and in its anxiety to provide a service for the nation it should certainly approach the Prime Minister and ask him to intervene personally or through some other responsible person with a view to the reopening of negotiations.

Dr. Dain asked that this be turned down. Although it came from Birmingham he dissociated himself from the motion. He reminded the meeting that the Prime Minister and the Chancellor of the Exchequer backed with their signature the resolution which Mr. Bevan brought forward in the recent Commons debate. It was not for them to go either to the Minister of Health or the Prime Minister.

Dr. J. A. Gorsky (Westminster and Holborn) suggested that it would be unconstitutional to go to the Prime Minister.

Dr. Gould, in reply, said that doctors who were not representatives felt that this was not the time to sit still and glare at Mr. Bevan. If the procedure suggested was unconstitutional he was very sorry, but it should not stop them from doing it.

The motion was lost by a majority.

Postponement of Service

Dr. Leslie Hartley (Guildford) moved:

That in view of the recent plebiscite result . . . the Representative Body, whilst agreeing with a comprehensive health service available to everyone, requests that it should be postponed until the necessary hospitals and other facilities have been built and equipped, and the personnel for a complete service have been trained.

The Service at present was "an empty egg-shell." He could not believe that 41,000 doctors had voted against the Act in its present form only on grounds of objection to State service; they must have had grave disappointment and misgiving in their hearts as well concerning the possibility of such service having in view the shortage of nurses, the overburdening of general practice, and other considerations. Doctors were skilled in prognosis, and they had given this Act a bad prognosis. They feared that the child would be stillborn. Nevertheless, Mr. Bevan intended to hand them the baby, dead or alive.

Dr. Helme (Guildford) referred to the lack of personnel. They had been told by the Government that this country was in an extremely

serious economic position, largely owing to lack of manpower. If this Act came in, in view of the lack of facilities and manpower, they would be doing a great disservice if they tried to work it. It would call for the employment of vast numbers of Civil Servants, and it seemed really a patriotic duty on the part of the profession to let the people understand that the nurses, ward maids, and the like were just not available for running a service like this. The production of food was far more important to the nation than the production of a vast bureaucratic scheme of this kind.

Dr. D. A. Robertson (Reigate) said that if the Government wished to provide a service it should build health centres and hospitals. This thing which was being rushed upon us had only a political background.

The motion was carried, but a further motion by the Hartlepool calling for the postponement *sine die* of the implementation of the Act, and for the Association to draw up in outline a scheme of medical service which could be carried out, was lost.

Dr. W. N. Leak (Mid-Cheshire) said that the Government was in trouble because it had been trying to do too much and to go too far. That was the situation with regard to this Act. It attempted something for which neither the personnel nor the equipment was available.

A motion by Reading calling for the suspension for two years of the suggested arrangement for the correction of maldistribution of doctors (except that of financial inducement to under-doctored areas), and its review at the end of that time, was lost. The following was carried on a motion by the City of Edinburgh:

That inasmuch as the medical profession believe that a complete health service cannot be made available to everyone in July, 1948, because of lack of staff and other facilities, this meeting is of opinion that particular consideration should be given in future negotiations to the possibility of introducing the Service by stages, as this becomes feasible.

Alternative Schemes

Dr. A. C. de B. Helme (Guildford) moved that in the event of a complete deadlock the Council should be instructed to draw up and submit to the profession an interim scheme based on the Marylebone resolution passed by the Representative Body in December, 1944.

(The Marylebone resolution read: "That health legislation should proceed by evolution, and the Representative Body is of opinion that the objects aimed at will be achieved by completion of the N.H.I. service to embrace institutional, specialist, and all auxiliary services; and, when this is accomplished, the expansion and extension of N.H.I. to dependants of those insured and to others of similar economic status." It was carried by 113 to 106.)

On July 5 they would be presented with alternatives, either with postponement or with something in the nature of a fraud on the public. In 1929 and 1931 the Association requested that the National Health Insurance Act should be amended to include dependants of insured persons and others of like economic status. The Marylebone resolution offered an opportunity for acting in conformity with the Association's views and also with what might reasonably be carried out. As for hospital services, if the hospitals were given something like £15 million a year as a grant they could do a great deal to improve their facilities and eliminate their shortages. Possibly for every pound subscribed by the public the Government might offer an equal amount. With regard to general practitioner services, dependants of insured persons and certain other dependants might be included. As for specialists, the increase of the money to the hospitals would undoubtedly help the specialist situation. Some such scheme would at all events be practical and would be likely to lead in the future to something really good. It would safeguard the voluntary hospitals, and it would afford time for the proper consideration of a health service which would commend itself to the whole nation.

Dr. Murray-Browne (Gloucestershire) said that the profession had been faced with a good many negatives. They would like a positive statement of what could be achieved.

Dr. Woodhouse (Harrow) said that her Division, at a meeting with an attendance of 80, with only three dissentients, had recommended that the Council be instructed to prepare an interim scheme comprising an extension of the present panel system to cover all persons in need of such service, on the lines of the scheme published by the Association under the title "Proposals for a General Medical

Service for the Nation." Mr. Bevan was in a tight corner. Would it not be a great kindness on the part of the medical profession to get him out? If they co-operated to make an alternative service a magnificent success and put it forward as an interim scheme perhaps it would not be unacceptable to the Government. It might end this unhappy impasse while at the same time making for the independence of the profession.

Dr. David Haler (Guildford) and one or two other representatives asked that consideration be given to the Marylebone scheme as a practical method of alternative service should the deadlock persist.

Dr. E. A. Gregg said that in so far as this resolution meant the organization of a nation-wide scheme for the provision of medical service for the people, the Association had already published its views. Everyone was familiar with the Association's proposals to give a medical service for dependants of insured persons and others of similar economic status. For a long time those proposals fell on deaf ears so far as the Government was concerned; it was only in recent times that they had shown this great interest in the subject. But if the resolution was directed to what the doctors should do in the interval before their present problem was solved, an Association committee under the chairmanship of Dr. F. Gray had sat for a long time endeavouring to frame schemes. The material this committee had gathered together had been circulated, but it was found that there was no general desire for a standard form of medical service all over the country; various parts of the country preferred to have schemes of their own. Some favoured an extension of existing public medical services.

The Guildford motion was carried.

Midwifery Services

Dr. R. W. Rae (North Staffordshire) moved that the Council advise all practitioners that it is not in accordance with the policy of the Association to accept election to the proposed Local Obstetric Committees; to which Dr. N. J. P. Hewlings (Oxford) moved to add the words: "Until further negotiations have taken place between the Royal College of Obstetricians and Gynaecologists and the Association." Dr. Hewlings felt that means should be found for preventing the standard of general midwifery practice falling to danger level.

Dr. Dain said that advice had been issued on this point, but they had not taken the step of telling members that they must not accept appointment.

Dr. Isabella Little (Oxford) said that no one with knowledge of the varying standards of midwifery in this country would deny that there were very large problems involved in this matter, and instead of shutting the door completely to the appointment of such committees she hoped that further discussion with the Royal College would take place.

Dr. J. A. Gorsky supported the North Staffordshire motion. The instruction had been sent out by the Ministry of Health to Local Executive Councils that they appoint an *ad hoc* committee, to include two general practitioners, which would review the experience of doctors desiring to do midwifery work, and if they considered any doctors were not sufficiently experienced they might call upon them to undertake further training. It was therefore a matter of importance that doctors should not take office on these *ad hoc* committees. If he himself, although actually he did not practise midwifery, were instructed by local practitioners to undertake another course of training he might be inclined to institute proceedings for libel.

The Oxford amendment was lost and the North Staffordshire motion carried. A further motion by Wakefield protesting strongly against the "closed panel" for midwifery under the new Health Service was also agreed to. Dr. D. L. S. Johnston (Halifax) asked why, if doctors by virtue of their qualification from their university were entitled to practise midwifery in Scotland and Northern Ireland, they should not be allowed to do so in England. This might become a precedent for some other limitation on general practice. It might be declared in time that a general practitioner was not to be allowed to open an abscess, and ultimately his work might be limited to signing forms.

A series of motions bearing on the presentation of the profession's case to the public was referred to the Council.

Proposed Withdrawal of Certification

Dr. H. W. Donovan (Birmingham Central) had a motion on the paper "That as this is a fight for freedom which cannot be conducted by appeasement or kid-glove methods, the Representative Body should press for withdrawal of certification prior to July 5." He said that this was a weapon which would put them on equal terms with the Minister.

Dr. Dain asked the meeting to remember that they were a body of responsible people under contract to give service to

the insured, and part of such service was the issue of certificates. If this was to cease, it could only be done after notice, and the notice would more or less take them to July 5. Therefore it was not a means of forcing the issue earlier. This was a course not open to them to take unless they individually risked a summons for breach of contract.

Dr. H. H. Goodman (Newcastle-upon-Tyne) said that doctors did not want to offend anyone, least of all their patients. But the refusal of all forms of certification, other than death certificates, would be a sort of token resistance. It would produce some chaos in administrative ranks and expedite the solution of the whole matter. The onus would be on the Government to find some alternative method.

Dr. Donovan said that it was true, as Dr. Dain had stated, that they could not break their contract, but they could resign straight away. He did not believe patients would suffer anything like so much as they would suffer if the Act could not properly be worked.

The Birmingham motion was lost by an overwhelming majority.

Dr. W. V. Howells (Swansea) brought forward a somewhat different motion:

That this meeting considers it essential, if the profession is advised not to accept service after July 5, that no certificates other than infectious diseases notifications, certification under the Lunacy Act, and death certificates be signed by any member of the profession.

They wanted to make it clear that after July 5 they would not withdraw their services for sick people, but they could not carry on their practices exactly as they were before.

Dr. J. L. McKenzie Brown (South-West Essex) said that his Division considered that if they were instructed to refuse service after July 5 no certificates of incapacity should be issued.

Dr. R. W. Cockshut (Hendon) said that if after July 5 they were to carry on the medical services of the nation exactly as in the past Mr. Bevan might well say, "We will see who is going to get tired first." He agreed that they could not stop certifying now, but they must warn the public that if they allowed this thing to come to a conflict a lot of people would have to get hurt.

Dr. E. A. Gregg (Deputy Chairman) entirely disagreed with what had just been said. There could be no more unwise action from the standpoint of policy than to withhold from patients a statement regarding their illness if they asked for it. He was not saying that they should fill in official forms, but the withholding of a private form certifying unfitness for work would only embarrass the patient, and might indeed cause difficulty in providing the ordinary necessities of life for a sick person. That would be a grave reproach to a great profession. ("Hear, hear.") This "paltry act" of withholding a necessary certificate which would have enabled a patient to make such claim as he could make would do the profession no good with the public, and it would be contrary to all the instincts they had inherited in their professional traditions (Applause.)

Dr. Dain said that it was impossible for a body of gentle people to contemplate making progress in a dispute at the expense of their patients. He had never heard such an atrocious proposal put up as that they should refuse to order the food which a sick person required. Dr. Cockshut had said that somebody was going to be hurt—yes, but not their patients. Their patients would always come first. They were going to fight this battle fairly with proper regard to their responsibilities to their patients. He was amazed that such a suggestion as that they should refuse certificates should have been produced at that meeting. (Applause.)

Dr. J. A. Pridham spoke of the great practical difficulty of refusing certificates.

Dr. Helme (Guildford) thought that, nevertheless, there was a good deal behind these resolutions. There was no intention to hurt people—no one had used the word "hurt" except Dr. Cockshut—and this weapon could be used reasonably. He thought it better not to turn the resolution down but to refer it to some other body which could give it consideration "without sentimentality."

Dr. Howells replied that in bringing forward this motion his Division had not intended to cause hardship, but it felt that, apart from the exceptions mentioned in the resolution, certificates should not be issued.

The Swansea motion was rejected.

Democracy and Freedom

Dr. Geoffrey Evans (Marylebone) submitted a motion approving the statement of the National Executive Committee of the Labour Party, published on March 3, namely:

"... Democracy cannot live without freedom of speech, press, and organization; without the right to protection against arbitrary arrest, the right of appeal to a non-political judiciary."

The motion went on to propose that the National Executive Committee be asked if the profession might rely on them to support the B.M.A. in obtaining these freedoms for the medical profession under the National Health Service. Dr. Evans said that this motion was no manoeuvre for appeasement. The fact was that they were a strong and united profession on the principles for which they stood. Nevertheless, in order to achieve their ideals they required public support, and approach to public opinion as a whole was difficult to make. The first section of the community with which to make contact was obviously the Labour Party because it claimed to be representative of the working class, and doctors themselves were working men and women. He knew that they had strong support in some quarters of the Labour Party, and the motion drew attention to the fact that the profession and the Labour Party subscribed to the same principles.

The motion was carried.

A motion by North-East Essex calling for a nation-wide scale of minimum fees for ex-insurance patients, to be recommended by the Association in the event of refusal of service, was referred to Council. Two motions by Plymouth were carried, one that the appointment of medical representatives to bodies set up for administration of the Act should be made only after agreement with the elected representatives of the profession, and the other that the Act must be amended to guarantee freedom of expression to doctors in all matters relating to the clinical and administrative aspects of the Service. South Essex desired the remuneration and conditions of service for junior staffs in hospitals to be considered by the Spens Committee at the earliest possible moment. Dr. Dain said that he was prepared to agree that this should be considered, though he thought the reference to the Spens Committee should be left out because that was not the best method of determining the remuneration of hospital residents.

Consultants Liaison

Mr. G. Whyte Watson (Bradford) asked that there should be adequate provincial representation on the proposed London Liaison Committee, and that the new committee should represent all consultants. Provincial consultants, he said, felt that something should be done to safeguard their interests.

Dr. Dain said that Bradford was under a misapprehension. The London Consultants Committee was set up to consider conditions in London, and he hoped Bradford would set up a committee for its own area. It was expected to see similar committees in different areas, and they would report to the Association's central committee. They were in the process of establishing permanent machinery for the discovery of consultant and specialist opinion in all areas.

Lord Horder (Chairman of the London Consultants Committee) said that the London Liaison Committee was only established formally on the previous day. The committee arose as the result of a desire to carry on the positive effort of standing by their general practitioner colleagues in the present fight. It came about partly in response to an invitation from the Association Council to the Marylebone Division, but he hoped it was obvious that Marylebone did not consider it had a corner in consultant and specialist work and opinion. They valued their provincial colleagues too much to stand in the way of their doing in various centres what Marylebone was doing in London.

The Bradford motion was withdrawn.

Miscellaneous Motions

At this late stage in the meeting a number of motions were put from the chair without discussion, and the following were carried:

South-East Essex: Deprecating the abusive comments made by the Minister of Health upon their democratically elected representatives.

Greenwich and Deptford: Instructing the Council, the profession having expressed its emphatic view through the plebiscite, not to be influenced by any "quislings" however exalted they might be.

South Bedfordshire: Reaffirming that the opposition of the profession to the National Health Service Act in its present form is not connected with parliamentary party politics.

Derby: Pledging support to the Council in all measures considered necessary to safeguard the essential freedom of the profession.

Derby: Warning the Government and the public that medical facilities and personnel are at present entirely inadequate for a full service, the immediate implementation of which will result in a less efficient service than now obtains, and may well lead to a state of chaos.

Doncaster: Supporting the action of the Council of the Association in any action it may take.

And finally, a bouquet to the Representative Body itself.

Oxford: Reaffirming confidence in the deliberations of the Representative Body, and expressing its belief that any recommendations it might make would be based on fair and reasonable discussion.

Regional Hospital Boards and Local Executive Councils

The Chairman of Council moved the following recommendation:

That medical members of Regional Hospital Boards and Local Executive Councils be requested to continue their membership of these bodies for the present.

Dr. Dain said that the question had been considered whether the medical members of these bodies should be asked to retire, and it had been decided to recommend that they remained. They were bodies of which the Association had approved in its policy, and they were looking at the administrative details of the new Service. It was thought that medical members should be present to take part in such administrative construction.

Dr. J. M. Christie (Finchley) had an amendment which made the continuance of membership contingent upon the Government reopening negotiations with the representatives of the profession. He considered that the Council's recommendation would be open to misrepresentation. Medical members of Regional Boards and Executive Councils had been appointed to administer the Act as it stood, and the plebiscite had condemned the Act. An anomalous position might arise if medical members were asked to continue to serve. A hostile Press might well point out an apparent inconsistency, and interpret it in the sense that the profession no longer wanted to stand by the plebiscite.

Dr. Dain hoped the meeting would not agree to this amendment. At any moment it would be possible to change the policy if circumstances suggested that it was the proper thing to do. He deprecated laying down the conditions under which these medical members might be allowed to remain or asked to withdraw.

The Finchley amendment was lost, and the Council's recommendation accepted. Dr. Dain agreed on the amendment of the Isle of Wight to extend the recommendation to cover Health Committees of local authorities.

This completed the business, and the meeting ended after according votes of thanks to the Chairman and Deputy Chairman.

SPECIAL PANEL CONFERENCE DEMAND FOR CHANGES IN THE ACT UNANIMOUS DECISIONS

A Special Conference of Representatives of Local Medical and Panel Committees was held at B.M.A. House, London, on March 16, the day before the Special Representative Meeting. The chair was taken by Dr. J. A. Brown (Birmingham), and almost all the insurance areas of Great Britain were represented. The President of the British Medical Association Sir Hugh Lett, Bt., was on the platform. A visitor was Dr. P. J. Delaney, newly appointed secretary of the Irish Medical Association, who, in reply to a welcome, said that in the Irish Free State the fight of British doctors was viewed with the greatest possible sympathy. "We can do little for you, but at least we wish you well."

The Governing Resolution

A resolution identical with the one to be moved on the following day at the Representative Meeting was proposed on behalf of the Insurance Acts Committee by Dr. E. A. Gregg:

That this Special Conference of Local Medical and Panel Committees, reaffirming the whole-hearted desire of the medical profession for a comprehensive health service available to everyone, urges that in the public interest such changes should be made in the

National Health Service Acts of 1946 and 1947 as are necessary to maintain the integrity of Medicine and to prevent doctors being turned into State servants, with harmful consequences to patient and doctor alike. The Conference therefore expresses the hope that the Government will make it possible for the profession to co-operate by making such changes, and states its view that it is not in the best interests of the public or of Medicine for members of the profession to enter the Service until such changes are made.

Dr. Gregg: "We have reached a further stage in our journey. The various steps we outlined in our programme have been taken one by one. We have had the process of discussion among ourselves and a long series of talks with the Ministry. We have furnished to the profession an account of them and the Minister's reply. We have taken a plebiscite, which was conducted in such a way that no one can ever know how an individual practitioner voted, and by an overwhelming majority in every branch of the profession the vote was against approval of the Act as it now stands. The Government proposes to start this service on July 5, and we as a profession—not the negotiators only, not the leaders of the B.M.A.—have said that we do not approve and do not propose to take service under it. I assure you that there are in preparation ample arrangements to enable every practitioner to look forward with confidence to the difficult period between now and July. If the Minister does not get the doctors by the appointed day he has only himself to blame. Our negotiators have tried patiently to help him, but on all essential points he has consistently refused to consider any modification. It is stated that he has made concession after concession. As a negotiator myself I cannot recall a single concession he has made beyond his proposal to allow consultants to have private beds in hospitals, a proportion with a ceiling and a proportion with no ceiling, 'provided that the hospital needs of the community are met.'

"We are prepared as a profession to stand our ground and resist coercion and all attempts to place us by economic pressure in service under this Act in its present form. The Insurance Acts Committee thought it right that this Conference, which for a long period of years has endeavoured by constructive criticism and suggestion to guide insurance practice, should be called to offer its opinion on the resolution which will be placed before the representatives of the whole profession tomorrow. The resolution has been so worded as to be non-provocative. If the Government want to think again we are ready to listen to what they have to say.

"At the present moment one thing is of the greatest importance to us—to stand in proper relationship to the public—and this resolution is so framed as to enable the public to realize that we as doctors are perfectly reasonable people. There is no truth in the suggestion that doctors are sabotaging the Act. We want a comprehensive health service—we have been agitating for it for years. Only the Government itself is in the way of that ideal by having introduced into this Act certain elements which make it impossible for us as a profession to accept it as satisfactory. Throughout the Act and the speeches supporting it there runs the implication that it is but a step to a goal, and that the goal is a whole-time salaried State service. Some of you will say this resolution is not strong enough, but I hope you will allow it to stand in its unprovocative form, expressing as it does to the public at large the desire of the profession for the setting up of a national health service in which it can take a satisfactory part." (Loud applause.)

An amendment stood in the name of Edinburgh to insert after the words "available to everyone" the following:

declares its willingness to co-operate with the Government and to reopen negotiations through its representatives towards the establishment of such a service, but urges that in the public interest such changes should be made in the Acts of 1946 and 1947 as are necessary to maintain the independent status of Medicine and to prevent doctors being turned into State servants with harmful consequences to the patient and doctor alike

and then continuing with the last sentence of the I.A.C. resolution.

Dr. N. B. Stewart said that Edinburgh was as steadfastly opposed to the Acts in their present form as the rest of the profession, but it felt that the recommendation was just an expression of opinion and hope; it was not positive enough. Some more clear indication of the profession's attitude should be given for the benefit of the public at large. With the unity

demonstrated in the result of the plebiscite they were in a strong position to make the declaration of willingness to co-operate in the terms of the Edinburgh amendment. This was no sign of weakness—far from it.

Dr. Gregg said that he did not think the Edinburgh amendment was any improvement on the resolution.

Only two hands were held up in favour of Edinburgh's amendment, which was heavily lost, and a similar fate befell a Nottinghamshire amendment which proposed a rearrangement of the resolution.

The resolution as moved by Dr. Gregg was then put. No dissentient hand was raised, and assent appeared to be unanimous.

The Next Step

Dr. F. E. Gould (Birmingham) moved that the Negotiating Committee should approach the Prime Minister forthwith with a view to reopening negotiations. The whole country, he said, was waiting for the profession to give a lead, and, armed with the plebiscite result, it could do so without fear of an accusation of weakness. The Prime Minister had said that he was willing to meet anyone. Let our leaders go to Mr. Attlee. "Negotiate," according to the O.E.D., was "to confer with another with a view to compromise or agreement."

Dr. Howie Wood (Isle of Wight) pointed out the danger of arriving at a conclusion on such a matter different from that which the Representative Body might reach on the following day. Dr. A. V. Russell (Wolverhampton) hoped that this suggestion would be turned down. Dr. A. Beauchamp (Birmingham) said that it was of no use both sides uttering the Molotovian "No." The Prime Minister had said in the House, in reply to Mr. Wilson Harris, "I am prepared to consider any suggestion put before me." Dr. J. A. Ireland (Shropshire) considered that to approach the Prime Minister would be futile.

The Chairman of Council (Dr. Dain), who was received with acclamation, said that although this motion came from Birmingham it did not have his approval and he dissociated himself from it entirely.

The motion was lost by a very large majority. Only about six voted in favour.

Transactions in Goodwill

Dr. D. L. S. Johnston (Halifax) moved a resolution reaffirming that the continuation of the buying and selling of practices was fundamental to the freedom of medicine, and that on this issue above all else the Association should stand firm. This was met by an amendment from Kincardineshire that the profession should consider agreeing to abolition of goodwill provided that all doctors on committees under the Act be directly elected by the profession, and that the committees elect their own chairmen.

Dr. G. H. Sedgwick (Rotherham) was in favour of the Halifax resolution. Surrender on this point meant loss of freedom, and having given up their freedom it would matter very little whether they were paid by salary or capitation fee. "If we are not prepared to stand for this principle the plebiscite is worth nothing at all." Dr. G. M. Goodwille (Norfolk) said that on the various principles to which the profession had declared its adherence nearly all, he thought, might have been conceded by the Russian Government to Russian doctors, except the ownership of practices. They had been told that this was a weak wicket on which to bat. On the contrary, as Public Relations Secretary in his Division, he had found it a strong one. Labour men in his area had seen the point in a manner which had surprised him.

Dr. Gregg described the Halifax motion as unwise because it was starting the setting up of priorities, "and we have not got that length." He hoped the decision would be left open.

The Kincardineshire amendment was rejected by an overwhelming majority, and the Halifax motion was disposed of by proceeding to the next business. A resolution by Cumberland asked the Conference to express the opinion that the Minister should not have the power to alter or add to the terms of service without consultation with the profession.

Dr. Gregg said that he thought this resolution, too, might be left to the future. On one occasion when a Minister broke faith with the I.A.C. an apology was received and a firm

assurance was given that such a thing would not happen again. If present difficulties were resolved and the Service was in operation there would be a body comparable with the I.A.C. which would discuss with the Minister matters pertaining to the Service and they would insist on the same position as had obtained under National Health Insurance.

It was agreed to refer the Cumberland motion to the I.A.C.

Public Relations

A motion by Newport asked that "immediate steps be taken to inform the public of the exact conditions on which the profession was prepared to enter the Service." Dr. A. C. E. Breach (Kent) suggested that this resolution be withdrawn. "Exact conditions," even if definable at all, were exceedingly complicated and technical. The public, of course, had a right to some sort of statement as to the profession's aims, but in its present form the resolution was thoroughly objectionable. Dr. W. Woolley (Bristol) also spoke against the proposal. It was for the Divisions, through their public relations committees, to do this work. Dr. J. T. McCutcheon (Glasgow) said that people wanted to know the policy of the Association, but it was very wrong to use the phrase "exact conditions." Dr. Gregg said that this was a question of public relations, on which a great deal of work had already been done, and a mass of material would be available and in the hands of the profession up and down the country.

The Newport motion was withdrawn.

Medical Cards

Dr. I. G. Innes (Hull) moved that practitioners be advised not to accept any medical cards under the Act until so advised by the Association. He understood that medical cards would shortly be issued.

Dr. Gregg said that this matter bristled with difficulties. The phrase "accept medical cards" was open to various constructions. It was a matter which would require consideration in connexion with the conduct of the campaign. Dr. F. M. Rose said that his Preston Committee was anxious to have some ruling as to what was to be done with these cards. If they were accepted and put aside did it not imply some acceptance of contract? Dr. Jope (I.A.C.) said that there was no present intention to issue medical cards and he suggested that it be referred to the I.A.C. Dr. Howie Wood hoped that if the motion was referred to the I.A.C. it would not be with the implied approval of the Conference.

It was agreed to refer the matter to the Committee.

The Independence Fund

Dr. Gregg, as chairman of the National Insurance Defence Trust, moved:

That this Conference endorses the action of the Trustees in voting the sum of £400,000 as an initial contribution from the Trust to the Independence Fund.

A great deal would be heard soon about the Independence Fund, which would provide the sinews of war for the conduct of the campaign. The Trustees of the Defence Fund felt that as insurance practitioners were to such a tremendous extent involved it was appropriate that they should support the Independence Fund to the utmost. It might not be necessary to use this money. Such money as was not required in carrying out the campaign and in providing assistance for hardship cases among loyal practitioners would be returned to those contributing in the proportion of their contributions.

The motion was carried unanimously.

Terms and Conditions of Service

Dr. W. Parker (Swansea) moved that in view of the promise given that practitioners should have six months to study the terms and conditions of service, the fullest details of the Service should be published, as affecting the whole profession, before any one section was asked to join. The appointed day was now little more than three months ahead.

The Swansea motion was carried unanimously.

Alternative Service

Dr. P. Y. Lyle (Southport) moved that the Conference welcome a definite assurance that there was in existence an alternative plan for the medical services of the nation should the profession be advised not to accept service under the Act.

Dr. Gregg said that if in spite of the resolutions of the Conference and those of the Representative Meeting on the morrow no reopening of relations between the profession and the Government took place, and they were faced with a struggle, the question of how practices were to be conducted would undoubtedly arise. A committee was set up which had gone into the whole question of the conduct of practice in the event of a dispute of this kind with the Government, and the report of that committee had been circulated to all Panel Committees. It appeared that Panel Committees did not wish to have a stereotyped standard method applied all over the country, and that this was a matter which should be determined in each locality.

Dr. Lyle found the reply disappointing, and pressed his motion to a division, on which it was carried by 99 to 56.

Dr. D. G. Buchanan (Rutherglen) moved that the B.M.A. Council be asked to frame and publish to the profession at the earliest possible moment its alternative to the National Health Service scheme.

Dr. Gregg: Our alternative is the National Health Service scheme with the changes in it for which we have asked and of which you are all aware.

It was agreed to pass to the next business, which was a motion by Cheshire asking that fresh consideration be given by the Council to the possibility of a National Health Service divorced from direct political control.

Dr. Gregg reminded the conference that the question of a "corporate body" had been argued, but the decision had been in favour of a scheme administered by a Government department. There did not seem to be much good in going over the old ground.

Here again it was agreed to pass to the next business.

Service on Local Executive Councils

Dr. A. C. E. Breach (Kent) moved as a recommendation to Local Medical Committees:

That they inform those medical practitioners whom they have appointed to serve on Local Executive Councils that they regard such appointments as provisional, and that they will expect these members to place their resignations from the Local Executive Councils at the disposal of the Insurance Acts Committee.

He said that this was an attempt to express the utility of the profession and their loyalty to their leaders. The Local Executive Councils were one of the principal bones in the skeleton of the Act and of first-class importance to its whole structure. The recommendation would help to dispel the illusion that acceptance of membership on the Executive Councils was equivalent to acceptance of service under the Act.

The motion was carried.

The Spens Committee

A motion by Birmingham, and similar motions by Warwickshire and Dudley, read:

That the Minister of Health having agreed to accept the Spens Report on remuneration for general practitioners, the proposal for payment to doctors in his statement to the profession should be referred to that Committee for their consideration.

Dr. A. Beauchamp, in moving, said that this would not cross any decision of the Representative Meeting. He was aware that the Spens Committee was no longer in existence but it could be reconstituted. He had hoped that it would be a permanent body for the reference of matters connected with remuneration.

Dr. Gregg said that he could see no value in this motion. They had had the Spens Committee report, had considered it and understood the yardstick, and could apply it quite easily.

Dr. Dain also disagreed with this suggestion. The Spens Committee was set up for a particular purpose, to discover the range of income which a general practitioner should be able

attain. Its report had been accepted by themselves and by the Minister. When the Service was established the question of terms would be debated between the Government and themselves by means of the Whitley machinery so as to ensure that there was a proper relation between the remuneration of the different branches of the profession. That was a business they ought to keep in their own hands.

The Birmingham motion was lost by a large majority. A further motion on remuneration was by Swansea, that the capitation fee should be determined independently of the demands of the basic salary on the global sum. The mover, Dr. W. Parker, said that, while it was hoped that if the new service was satisfactorily established the number of doctors coming into it would increase as the years went on, this ought not to mean any diminution in the capitation fee. "Let us have a fixed capitation fee, and we shall know where we stand." Dr. Gregg reminded the Conference that the remuneration set out by the Ministry had not by any means been accepted. Moreover, he did not like the reference to basic salary.

It was agreed to pass to the next business. A resolution was moved by East Sussex declaring that should negotiations be resumed the I.A.C. should insist that, on the coming in of the new Service, provision should be made for the prompt registration of every person with a doctor. Dr. C. M. Stevenson (Cambridge) asked what, under this proposal, would happen to the principle of free choice. Dr. Gregg also criticized the resolution and said that such matters would have to be dealt with at a later time. Undoubtedly the problem would arise in connexion with the Health Service in a way in which it had not arisen under National Health Insurance.

The resolution was withdrawn.

Dr. F. M. Rose (Preston) had a motion calling upon the Conference to reaffirm its confidence in the Negotiating Committee. The mover was met with cries of "Agreed" before he could begin his speech, and the motion was unanimously carried.

CONFERENCE OF REPRESENTATIVES OF SCOTTISH DIVISIONS AND LOCAL MEDICAL AND PANEL COMMITTEES IN SCOTLAND

A fully representative meeting of Scottish Divisions of the British Medical Association was held in Edinburgh on March 10. The Conference, which was held in the Scottish House of the Association, was attended by representatives of the Scottish Constituencies in the Representative Body, representatives of the Local Medical and Panel Committees, members of the Scottish Committee of the B.M.A., and members of the Insurance Acts Subcommittee (Scotland). It was agreed that the Council's recommendations be adhered to, emphasis being laid on the fact that these recommendations were in themselves sufficient indication that the Association was prepared to negotiate, but that the first steps should be taken by the Government.

Dr. J. B. Miller, Bishopbriggs, presided, with Dr. W. D. Frew, Kilmarnock, as deputy chairman. Dr. Miller's first action was to extend a warm welcome to Dr. H. Guy Dain, chairman of Council. In his reply Dr. Dain said that it was important that they should all have every opportunity of understanding the situation, knowing what was going on, and looking to the prospect in front as well as at what had happened in the past. They had the 1946 Act for England and the 1947 Act for Scotland and on the points with which they were most intimately concerned there was very little difference between the two. They hoped that, whatever alterations could be made in one Act would be made in the other.

Statements on the discussions on the Scottish Act between the Scottish Negotiating Committee and the Department of Health for Scotland were introduced by Dr. A. F. Wilkie Millar, chairman of the Scottish Negotiating Committee. "The Scottish Negotiating Committee had no specific remit," he said, "but it has always been understood that we would not discuss, with a view to arriving at any agreement, matters which were properly of U.K. concern. These are being left to the Central Committee. Our talks were on matters arising out of the Scottish Act, particularly with regard to administrative arrangements and regulations made under that Act."

General Practice

Giving the report of the General Practice Subcommittee of the Negotiating Committee, Dr. I. D. Grant, its chairman, referred to the fact that succeeding chairmen of the Executive Councils would be nominated by the Councils themselves, the first chairman, appointed by the Secretary of State, holding office for three years.

Discussing partnerships in relation to the suggestion that there would be a maximum number of 4,000 patients on any one list, the Department had agreed that a partnership of two might have 8,000 people on their general list but one partner could have 5,000 and the other 3,000. The Department of Health had concluded that, on the basis of 95% being the appropriate proportion of the United Kingdom population likely to avail themselves of the Service, the appropriate figure for Scotland could be regarded as 96%.

Dr. Dain and Dr. Joje explained the method of distributing the Central Pool and pointed out that there were already 20,000,000 insured persons, so there was no question of a ridiculously small proportion of the people being on the lists at first.

Several speakers questioned the wisdom of considering amendments at that stage and it was agreed to proceed to the next business. There followed some discussion on the Maternity and Consultant Services and on the special problems of the Highlands and Islands.

The meeting then passed to the consideration of the motion, formally moved by the chairman, that the following recommendations of the Council of the Association to the Special Representative Meeting, March, 1948, be received:

"(a) That the Representative Body, reaffirming the whole-hearted desire of the medical profession for a comprehensive health service available to everyone, urges that in the public interest such changes should be made in the Acts of 1946 and 1947 as are necessary to maintain the integrity of Medicine and to prevent doctors being turned into State servants, with harmful consequences to patient and doctor alike. The Representative Body therefore expresses the hope that the Government will make it possible for the profession to co-operate by making such changes, and states its view that it is not in the best interests of the public or of Medicine for members of the profession to enter the Service until such changes are made."

"(b) That an Independence Fund be established to help to finance the profession's activities during the present dispute with the Government."

"(c) That medical members of Regional Hospital Boards and Local Executive Councils be requested to continue their membership of those bodies for the present."

Dr. Dain said it might be appropriate that he should say something about the present position.

The plebiscite figures were interesting in that every type of practitioner regarded the present Act as unsatisfactory. People like medical officers of health and medical research workers had all, by a large majority, decided that the Act was unsatisfactory.

"Our aim," he declared, "is the establishment of a service in which we retain our professional independence. It is better said like that—as a whole—rather than by speaking of individual things like losing goodwill, or direction, or basic salary."

Explaining what he meant by professional independence, Dr. Dain said he had in mind such things as the power of the Minister to do anything he liked, change anything he liked, just by putting a paper on the table of the House of Commons to say he had done it, so that unless someone got up and raised a row in the House nothing could be done about it. This situation could be modified without destroying the Act or the Service if they proceeded about it in the proper way.

These and other matters could be dealt with in the Act without destroying the framework of the Service, and Dr. Dain hoped that the Representative Meeting would express views along these lines. He hoped that they would be able to agree some day with the Government, or with some Government, on a form of service in which their freedoms as well as the patients' and the Minister's were properly provided for.

Suggested Amendments

Dr. D. S. Robertson, Edinburgh, put to the meeting an amendment asking that a clause be inserted in the Council's recommendation to the S.R.M. to the effect that they were

willing to co-operate with the Government and reopen negotiations, this amendment being later altered to replace the word "reopen" with the words "take part in." Similar amendments from the City of Aberdeen and Lothian Divisions were merged with the Edinburgh one. Dr. Robertson emphasized that the amendment left intact the main part of the Council's motion, but it emphasized in a positive rather than a negative way their desire to participate in a health service which would be fair to the profession and good for the nation.

Dr. J. Inglis Cameron, Glasgow, led several speakers in disapproving of the Edinburgh proposal. Dr. Cameron said that offering to take part in negotiations would be taken to mean that they were giving way.

Prof. R. S. Aitken, Aberdeen City, said the Aberdeen Executive felt that from the position of strength in which the plebiscite placed them they ought to approach the Government and offer to reopen negotiations.

Dr. Dain said the Council's resolution had been received by the public as a very statesmanlike resolution. He again deprecated suggestions for more fierce and warlike action and said that the Representative Body hoped the Government would make it possible for the profession to co-operate. He had heard nothing in the discussion that would improve the words of the motion.

The Edinburgh amendment was lost when put to the vote. The meeting also rejected two subsidiary amendments—one suggesting that the phrase "integrity of medicine" be replaced by "independent status of medicine," and another suggesting the addition of the words "and Parliament" after the word "Government" in the first clause of the Council's motion.

Proposing a motion by the City of Aberdeen that service under the National Health Service Acts should be accepted by the profession only when terms of the whole service, including those of the consultants and specialists, were known, Dr. H. G. McPherson, Stonehaven, said specialists had sided with the general practitioners in holding out against the Act and they wanted the assurance that the general practitioners would not accept service under the Act, or the amended Act, until the specialists had a chance of knowing their terms of service. Mention was made of the length of time it might take to have the report on the specialists' terms, but Dr. Dain gave an undertaking that everything would be done to see that the specialists and general practitioners' terms were properly related to one another.

Scottish Negotiating Committee

The meeting adopted a motion from Caithness and Sutherland asking that all future negotiations concerning administration under the Scottish Act should be dealt with by a Scottish Negotiating Committee in Scotland.

OPHTHALMOLOGICAL SOCIETY OF AUSTRALIA

The Ophthalmological Society of Australia will hold its eighth Annual General and Scientific Meeting at Perth, Western Australia, on Aug. 15-21, in conjunction with the sixth Session of the Australasian Medical Congress (British Medical Association). The Society would cordially welcome members of the British Medical Association Section of Ophthalmology. Intending visitors are asked to get further information from the Congress Office, 230, St. George's Terrace, Perth, Western Australia.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar.

Non-County Borough Councils.—Dartford, Radcliffe (limited to future appointments), Tottenham, Wallsend.

Urban District Councils.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Portlaid, Redditch (restricted to new appointments), Tyldesley.

Scottish Burghs.—Motherwell and Wishaw.

Meetings of Branches and Divisions

KENYA BRANCH

The Annual General Meeting was held in the Medical Research Laboratory on Feb. 5, with Dr. Paterson in the chair and 41 members present.

The Hon. Treasurer gave a report on the position of E.A.M.J. and proposed that the Branch give a grant of £20 to the Journal. This was approved. Officers for the ensuing year were then elected as follows: President: Dr. R. Guy Johnson (*vice* Dr. A. R. Paterson); President-Elect: Dr. E. A. Trim; Vice-President: Dr. Mary Harris; Hon. Treasurer: Dr. J. A. Carman; Hon. Secretary: Dr. A. McK. Fleming; Council: Dr. G. V. Anderson, Dr. A. R. N. Dhanji, Dr. R. S. McElroy, Dr. G. E. Nevill, Dr. A. R. Paterson (*ex officio*), Dr. P. G. Preston, Dr. A. T. G. Thomas.

Mr. Gay French moved that "this Branch of the B.M.A. deprecates strongly the action of the Colonial Secretary in granting indiscriminate priorities, especially to the groundnut scheme and the Army, which reacts to the detriment of the civilian population of Kenya, with particular reference to the recent grave shortage of nitrous oxide gas." This motion was unanimously approved. The meeting further instructed the Council to take such action as may be possible to rectify this, and further to take notice of the serious shortage of medical supplies in general in the Colony.

Dr. Johnson's presidential address took the form of a programme of two cinema films: (a) D.D.T. against Malaria, prepared by the Medical Department of Kenya; (b) Surgery of the Chest. Dr. Trim moved a very hearty vote of thanks to the President for the trouble he had taken to obtain and show these films.

LINCOLN DIVISION

A General Meeting of the Division to which all practitioners in the area were invited was held on March 5, with Dr. A. M. Maider in the chair. Thirty-two members and non-members were present.

The meeting considered Council's recommendations to the S.R.M., and the chairman read the resolution that was to be put forward. Dr. Wray thought the motion very mild and acceptable to everybody. Dr. Cheshire thought that of Council's four points the two important ones were ownership of goodwill and the question of basic salary. He proposed that the Division should instruct its representative that he should stand firm against any basic salary and against abolition of the buying and selling of practices. This was seconded by Dr. Semple. Dr. Wray thought that to stand by the buying and selling of practices was wrong particularly as all parties had supported the abolition and there had been a majority in favour of this at the previous plebiscite. Mr. Briggs said that most of us at that time had not studied the question sufficiently nor realized its implications, and the previous vote was therefore not of much value. Dr. Robertson thought that if Dr. Wray held such views he was not suitable to represent the Division. Dr. Wray said that as the Division's representative he would of course vote according to their wishes, but feeling as he did he could not get up and speak with conviction on the subject. He then offered to resign.

After discussion it was proposed and seconded that "this meeting has full confidence in Dr. Wray and that he should continue to represent us." This was carried by 19 votes to 7. Dr. Cheshire's proposition was then put before the meeting and was carried without dissent. Dr. Robertson proposed that Dr. Cheshire's resolution be sent up as a motion for the S.R.M. agenda and this was seconded by Dr. Wray. On a show of hands, the resolution was lost by 1 to 3. Next, the meeting approved the establishment of the Independence Fund. Finally, the meeting agreed that in other matters their representative should follow the lead of Council.

NORTH-EAST ESSEX DIVISION

Dr. Douglas Guthrie gave a B.M.A. lecture on "The Patient as a Factor in the History of Medicine" before a combined meeting of the Colchester Medical Society and the North-east Essex Division on March 4. The meeting was preceded by the regular monthly dinner of the Medical Society, to which members of the B.M.J. were invited.

Dr. Guthrie reminded his audience that while the stories of great advances in the history of medicine and surgery generally record the names of the doctors concerned, the names of the patients to whom their theories were tested were seldom mentioned. A few indeed were known and deserved honour, such as Mrs. Crawford who heroically permitted Ephraim McDowell to perform on her the first successful ovariectomy. There must be many such whose names are unknown. He then reviewed some instances, from an Egyptian mummy to Queen Victoria, where the names of the patients were known. Some, such as Joseph Meister, who had been successfully inoculated against rabies by Pasteur, though honoured in their day came to a tragic end. He also mentioned some of the medical men who had recorded their own experiences as patients—for instance Dr. Mark, who suffered from acromegaly, and John Hunter, who inadvertently inoculated himself with syphilis.

BRITISH MEDICAL JOURNAL

LONDON SATURDAY APRIL 3 1948

THE PUBLIC HEALTH LABORATORY SERVICE*

BY

G. S. WILSON, M.D., F.R.C.P., D.P.H.

Director of the Public Health Laboratory Service (Medical Research Council)

"Immer höher muss ich steigen,
Immer weiter muss ich schauen."—GOETHE.

In the codicil to his will, prepared in 1877, Dr. Milroy speaks of the importance of determining the part played by contagion in the development and spread of various diseases. "This can only be effected by the patient investigation of numerous *verified* and *authenticated* facts in various localities and regions, and under different circumstances and conditions, apart from all previous speculation and any mere traditional or customary beliefs." Though we have progressed a long way in our knowledge of infection since that time, these words might well be taken as its text by the Public Health Laboratory Service, whose aim it is, by a combination of careful and accurate observations in the laboratory and in the field, to interpret the various manifestations of contagious disease in the community and to discover the causative agents of those diseases that have so far remained obscure.

During the past ten years or so, mainly stimulated by the demands of war, the pathological services of this country have expanded greatly. New laboratories have been established, existing laboratories have been enlarged, and the number of persons engaged in pathological work has increased beyond expectation. Some of this development was the result of deliberate planning to counter emergencies; some of it was of an *ad hoc* and almost fortuitous nature, designed to meet the pressing demands of the moment. The bodies taking part comprised the Ministry of Health, the Medical Research Council, universities, local authorities, and private pathologists, each working towards a separate end and each acting to some extent independently of the other. What, may we ask, has the result been? Have we now got the pathological services that we need to fulfil the extensive obligations imposed by the National Health Service Act? Are our laboratories staffed by properly trained and experienced pathologists? Are the laboratories under Government control working in harmony with those owned by the universities? And is the great body of pathologists actuated by a desire not only to provide efficient help for the clinician and the medical officer of health but to carry research into the various fields where our knowledge is still deficient? These are some of the questions that need answering, and I feel the time has come to review our present position. It is difficult to appraise the situation as it now is without understanding

how it has come about, and I propose therefore to devote the major part of the time allotted to me to a historical retrospect of the gradual intrusion of the laboratory into the practice of preventive medicine.

[The lecturer then dwelt at some length on the studies of John Snow on cholera, William Budd on typhoid fever, and Villemin on tuberculosis, in order to illustrate how, by their pathological insight and epidemiological acumen, these pioneers of the pre-bacteriological era were able to prove as fully as was then possible not only that the diseases they investigated were contagious but that the contagion must consist of minute particles indefinitely reproducible in the body of the host.]

Development of Public Health Bacteriology

The rise of public health laboratory work must be traced to the stimulating influence of Sir John Simon (1890) and of his successors at the Local Government Board—George Buchanan, Thorne Thorne, and William Power. Simon held it necessary that special investigations should be promptly made in all parts of England wherever and whenever the local prevalence of disease afforded ground for apprehending the existence of epidemics or the prevalence of local, occupational, or other insanitary conditions. He also maintained that special laboratory researches should be undertaken by the department for the elucidation of obscure aetiological questions, and for bringing the data so obtained to bear on sanitary administration. Under his aegis a series of careful, minute, painstaking, and accurate field inquiries was made by officers of the Board into such diseases as enteric fever, scarlet fever, smallpox, and food-poisoning, supported by an increasing volume of laboratory work designed to control the quality of water, milk, shellfish, foods, and air. The administrative side of the organization that was built up and galvanized by Simon has recently been described by Sir Arthur MacNalty (1947, 1948a, 1948b) in his FitzPatrick Lectures to the College. I shall therefore content myself with giving a brief résumé of the gradual development of laboratory examinations in relation to public health and sanitary science.

Water

From the middle of last century onwards the chemical analysis of water came to be practised more widely, but from the hygienic point of view the results were disappointing. Several careful investigations into water-borne outbreaks of enteric fever combined to show that water which satisfied the strictest tests for chemical purity might nevertheless be capable of giving rise to serious disease. Cory

*The first of two Milroy Lectures (abridged) delivered to the Royal College of Physicians of London on Feb. 10 and 12.

(1881-2) relates how he tested the truth of this conclusion by adding known amounts of typhoid excreta to water and sending it for chemical analysis to Dr. A. Dupré of the Westminster Hospital. It was found that the addition of 3.5 gr. (0.23 g.) of a typhoid stool to a gallon (4.5 litres) of water caused a rise of only 0.02 part per million in the albuminoid ammonia. According to the standards then in vogue such a sample fell into Class I, comprising waters of extraordinary organic purity to which no objection could be taken. The position at the time was ably epitomized by Buchanan (1881-2) in the words: "The chemist can, in brief, tell us of impurity and hazard, but not of purity and safety."

From about 1882 onwards attempts were made by exponents of the rapidly developing science of bacteriology to improve on the methods of the chemists. Robert Koch in Germany, Percy Frankland at Dundee and later at Birmingham, and Emanuel Klein at the Brown Institute and St. Bartholomew's Hospital, among others, used the plate method for the quantitative estimation of bacteria in water. Gelatin was employed, and attention was paid to the total number of colonies developing and the proportion liquefying the medium. Little immediate progress, however, was made, but it began to be recognized that the potential harmfulness of polluted water was due to the micro-organisms it contained, and that the results of chemical analysis had their highest value in the light they threw on the quality of the water from the standpoint of bacterial contamination (Brown, 1890).

It soon became apparent that the attempt to gauge the degree of impurity of a water by the isolation from it of pathogenic organisms like the typhoid bacillus was technically too difficult and what we might call strategically unsound. Instead a search was made for the common intestinal organisms, which would act as indicators of excretal contamination. Again little progress resulted. It was left to Alexander Houston to show that it was not enough to demonstrate the presence of intestinal organisms in a water, it was necessary in addition to measure their numbers and so gain some idea of the degree of pollution of which they afforded an index.

Working with Klein (Klein and Houston, 1897-8), Houston found that crude sewage usually contained about 100,000 coliform bacilli per millilitre and about 10 to 1,000 spores of *Bacillus enteritidis sporogenes*. Together, Klein and Houston (1898-9) performed a very illuminating experiment. They obtained sewage from eight different sources, diluted it progressively with sterile water, and carried out chemical and bacteriological analyses on the mixtures. The results revealed that the bacteriological method was 10 to 100 times more delicate than the chemical, and led the authors to conclude that "chemistry, as usually applied, is powerless to detect a degree of pollution of water with sewage which, from the viewpoint of the bacteriologist, would be considered gross in amount."

This conclusion was soon substantiated in practice. For some years there had been a series of dropping cases of enteric fever at Chichester. The town was supplied from several wells. The water from all of them was apparently pure as judged by chemical methods, but when Houston (1901-2) examined them bacteriologically he found that most of them were contaminated with organisms of excretal origin.

During the succeeding years Houston expended his whole energy on developing and improving bacteriological methods for the examination of water. He studied different index organisms; he elaborated methods for their recognition and differentiation; he followed the rate at which

they died out in sewage under natural and artificial conditions; and he defined the particular type of information that each of them could give. From his appointment in 1905 to the newly created post of Director of Water Examinations to the Metropolitan Water Board till his death in 1933 he occupied a position of authority that none could challenge. It is as true now as it was fifty years ago when he made his first great contribution, that bacteriology alone of the laboratory sciences is able to provide the assurance of safety which is demanded of the water supplies of our great cities. Subsequent work, though it has refined the means for distinguishing between different members of the coliform group, has done nothing to impair the essential soundness of Houston's conclusions, and his methods are in daily use throughout the public health laboratories of this country.

It may be noted that systematic bacteriological examination of the water supply was begun by the Metropolitan Water Board in 1885, by Professor Rubert Boyce at Liverpool in 1898, by Manchester and Birmingham Universities and by the West Riding Laboratory about 1900, and by the University of Leeds about 1904.

Shell-fish

By 1895 it had become clear that shell-fish might serve as a vehicle for infection with typhoid fever. At the request of Dr. Thorne Thorne, who was then Chief Medical Officer of the Local Government Board, Dr. Bulstrode (1894-5) surveyed the conditions under which oysters and certain other edible molluscs were cultivated and stored along the coast of England and Wales, and in a later report (Bulstrode, 1909-10) he summarized the evidence incriminating shell-fish as carriers of enteric fever.

Though Klein (1894-5) was unable at first to distinguish between polluted and non-polluted oysters, he was helped by the work of Houston, and subsequently (Klein, 1899-1900) succeeded in demonstrating excretal pollution of cockles bought from a street hawker. He showed (Klein 1900-1) that cockles and mussels readily took up pathogenic organisms like the typhoid bacillus and the cholera vibrio from sea-water and remained infected sometime for days. It followed from this, and from the observation of later workers, that to ensure safety shell-fish ought to be laid down in non-polluted water for a few days before being marketed, so as to undergo a process of natural self-purification. For this purpose artificial tanks containing chlorinated water have come to be used for oysters and mussels (see Dodgson, 1936), and the purity of the shell-fish is gauged by the coliform count or, still better, by the faecal coli count using the 44° C. MacConkey broth fermentation test (Dodgson, 1938).

Sewage

Some of the early bacteriologists studied the flora predominating in different stages of decomposition and prepared the way for the so-called biological method of the purification of sewage. The story is told in Sir Woodhead's fourth Harben Lecture of 1897 and is continued in the reports of the Royal Commission on Sewage Disposal appointed in 1898.

Of late years the public health bacteriologist has been interested in the demonstration of pathogenic micro-organisms in sewage. Since the introduction in 1927 of Wilson and Blair's medium, and the subsequent development of further valuable liquid enrichment and solid selective media, it has become practicable to isolate pathogenic intestinal bacteria from highly contaminate materials like sewage. As a result typhoid and paratyphoid

bacilli have often been demonstrated in town sewage even in the absence of any known cases of enteric fever. This discovery is becoming of considerable epidemiological interest. It seems probable that the organisms are derived from subclinical cases or from carriers, and the problem now is to determine their precise origin. Already a start has been made, at Cardiff, by King (1944), who was able by examining sewage effluents from a factory to detect the presence of paratyphoid bacilli of a particular phage type, and then by examining the faeces of the individual employees to discover a symptomless carrier infected with the same type. The exploitation of this method for revealing unsuspected foci of enteric infection will be watched with considerable interest.

Milk

According to Newsholme (1936) Dr. Michael Taylor, of Penrith, first drew attention in 1858 to contaminated milk as a cause of fever, and in 1870 published the first recorded account of an outbreak of scarlet fever due to milk. In Norway, Homan and Harting, who practised in the town of Kragerø, described in 1859 an outbreak of dysentery spread by milk, and brought strong epidemiological evidence to show that the infecting agent was a living organism which had gained access to the milk by excretal contamination (Kohro, 1923).

The annual reports of the Local Government Board during the latter half of the nineteenth century contain records of numerous milk-borne outbreaks of scarlet fever, diphtheria, enteric fever, and diarrhoea, of which some of the most interesting refer to scarlet fever. In 1882 Power (1882-3) investigated the occurrence of multiple cases of this disease occurring simultaneously in several districts of central London, and ascribed the infection to milk coming from a particular farm in Surrey. He postulated that one of the cows in the herd must have been infected with the scarlet fever organism. He reached the same conclusion again three years later (Power, 1885-6a), when he traced another outbreak affecting several of the North London boroughs to milk from a farm at Hendon. Just before the outbreak three newly calved cows suffering from udder disease had been admitted to the herd from Derbyshire, and it is highly probable that one at least of these animals was suffering from streptococcal mastitis. Unfortunately another disease causing fever, constitutional disturbance, and a localized vesicular eruption spread through the herd soon after the arrival of these animals, and both Power and Klein concluded that this generalized disease—known as the Hendon cow disease—was due to the same streptococcal organism as was responsible for the scarlet fever cases in man.

Though Power and Klein have been severely criticized for confusing these two diseases, it is only fair to point out that they deserve a great deal more credit than they received. Power was almost certainly right in attributing milk-borne scarlet fever to the diseased udder of a cow, though it was not till fifty years later that he was vindicated by the observations of Bendixen and Minett (1938) on the occurrence of bovine mastitis caused by infection with the human type of haemolytic streptococcus—*Streptococcus pyogenes*. Klein (1886-7) was also right in concluding that scarlet fever was due to a streptococcus, which he called *Micrococcus scarlatinae*. He isolated this organism from the finger blood of four cases of scarlet fever during life and from the heart blood of one case after death. Klein's conclusions were confirmed shortly afterwards by Gordon (1898-9; 1900-1); but it was not till the extensive work of Dochez, Avery, Lancefield, and the Dicks in the United States and of Fred Griffith in this country during the second and third decades of the present

century that the aetiological role of streptococci in scarlet fever was finally established.

[The lecturer then described the gradual incrimination of milk as a carrier of tuberculosis, undulant fever, and epidemic respiratory and intestinal disease, and deplored the effect of Koch's pronouncement in 1901 at the London Congress on Tuberculosis that the bovine type of tubercle bacillus was relatively harmless to man. This led to discontinuance of the current practice of boiling milk, and put back the clock of pasteurization for many years. He ended with the following words.]

It is a sombre thought that our people are still suffering from the effects of an ill-considered authoritative pronouncement made nearly fifty years ago by a German bacteriologist to whom we, and the whole world, owe so much for the other services he rendered to medical science. We may perhaps recall the words of the book of Job: "Great men are not always wise: neither do the aged understand judgment."

On the laboratory side bacteriological methods of testing milk were not introduced till after Bang's discovery of tubercle bacilli in milk in 1884. Delépine at Manchester started examining milk for these organisms in 1892, and Sims Woodhead, Kanthack, and Klein were early in the field. Between 1896 and 1908 Delépine (1908-9) examined no fewer than 7,000 samples of milk for the Manchester Corporation; he found that of 5,320 samples of milk as delivered to the consumer 8.9% contained living tubercle bacilli.

In 1901 Park in New York drew attention to the "great bacterial contamination of the milk of cities," and Pakes (1909) reported that London milk contained over 3 million bacteria per millilitre. Savage, Delépine, and Thomas Orr, among others, laboured to devise some way of measuring the degree of bacterial pollution, but without much success. The value of the plate count was recognized as being limited, and no such clear answer was obtainable from the coliform test in milk as Houston had derived from its use in water examination. It was not till the concept of purity in milk was differentiated into its two components of cleanliness and safety that the failure of laboratory methods to protect the consumer became evident. It is now realized that by routine methods the bacteriologist cannot say, as he can with water, whether a given sample of milk is safe to drink. All he can do is to say whether the milk is of a reasonable standard of bacterial cleanliness and whether its keeping quality is likely to be satisfactory to the housewife. For this purpose much simpler methods, based on the reduction of certain aniline dyes and designed to estimate the total metabolic activity of bacteria in the milk, are sufficient.

Heat-treated milk forms an exception. The introduction of the phosphatase test by Kay and Graham in 1935 provided a means of assessing the degree of heat treatment a milk had received, improved the control of pasteurizing plants, and went a long way to ensure that only milk which has been adequately heat-treated and freed from the risk of causing human disease shall be offered to the public under the designation "pasteurized."

Food

Knowledge of the animal parasites that are conveyed by food was well advanced before bacterial food-poisoning had even been recognized. Thudichum in 1864 gave a detailed description of the helminths of animals, of the diseases they cause, and of the illnesses that may result in man if he becomes infected with them. Power (1879-80) recorded what was probably the first account of trichiniasis in England, occurring on board the reformatory school ship *Cornwall*. The diagnosis was made retrospectively by

microscopical examination of the muscles of one of the victims exhumed two months after death.

[The lecturer then recounted the steps that had led to the displacement of Brieger's ptomaine theory of food-poisoning by the belief that it was a specific infection with organisms of the *Salmonella* group; and told of the later definition by Daek and his colleagues (1930) of the staphylococcal toxin type of food-poisoning. He went on as follows.]

The great increase in food-poisoning during the second world war led to renewed interest in the aetiology of this disease; and, though much of the increase was traced to the presence of salmonellae in imported spray-dried egg, and to staphylococcal intoxication attributable to the low hygienic standards of communal feeding centres, the causation of many outbreaks remained obscure. Suspicion is now being cast on other organisms, and a great deal of research will be necessary before the full story is unfolded.

The diagnosis of food-poisoning can usually be made on clinical grounds alone, but laboratory investigation is necessary to define the particular bacterial agent concerned. Indeed, it is mainly as the result of systematic examinations of material from food-poisoning outbreaks that our present knowledge of some of the factors causing this disease has been gained. The value of field investigations has been greatly increased of recent years by the development of methods for the serological typing of salmonellae and the bacteriophage typing of staphylococci which can often throw light on the probable article of food responsible and the way in which it became contaminated.

Air

The observations of the mid-Victorian epidemiologists on the effect of overcrowding in favouring the spread of such diseases as typhus, cholera, and tuberculosis prepared the way for bacteriological investigations of the air as soon as it became evident from the work of Pasteur, Lister, Koch, Loeffler, and others that infectious diseases were almost certainly due to the action of living micro-organisms.

Systematic research on the bacterial content of the air was begun in Germany by Hesse, who published his records in 1884. Two years later Percy Frankland (1886), in this country, making use of Hesse's gelatin-coated tubes for the detection of organisms suspended in the atmosphere, and of gelatin plates for the detection of organisms attached to heavier particles undergoing sedimentation, found that bacterial contamination of the air was higher in the town than in the country, higher at street level than at the top of St. Paul's or of Norwich Cathedral, higher indoors if people were moving about than if they were still, and very high indeed in a crowded railway compartment.

Considerable work was carried out during the 'nineties, and at the beginning of the present century Gordon (1902-3) and Graham-Smith (1903) both made quantitative studies on the air of the House of Commons. Influenced by Houston's work on the value of coliform bacilli as indicative of excretal pollution of water, Gordon selected salivary streptococci as his index organisms, and by this means was able to show that during loud speaking in a closed room air-borne organisms derived from the mouth could be detected 40 ft. (12.3 m.) in front and 12 ft. (3.7 m.) behind the orator. Indeed, he found by examination of the air in the chamber that different speakers on the Treasury bench emitted their own characteristic salivary flora. The Chancellor of the Exchequer harboured a *longissimus* strain, the Prime Minister a *brevis*, and the President of the Board of Trade a haemolytic streptococcus (Gordon, personal communication).

The gradually increasing recognition of the importance of the carrier in the spread of infectious disease led to a

diminution of interest in the part played by air, and it was not till the study of Wells (1934) in the United States on the characters of air-borne droplets, and the observations in this country on cross-infection by Allison and Brown (1937) in fever hospitals, and by Leonard Colebrook and others in surgical wards, that it was revived. The old controversy between the supporters of Cornet and Flügge on the relative importance of dust and droplets was taken up again, and even the long-discredited work of Power (1880-1; 1884-5; 1885-6b) on the aerial dissemination of infection around smallpox hospitals began to be reconsidered.

To-day air-borne infection stands in the forefront of epidemiological and laboratory studies in public health work, and numerous teams are investigating the different modes of aerial spread and the measures that can be taken to control them.

Disinfection

The study of disinfection played a large part in the early laboratory work on public health. Even before the bacteriological era, Budd in 1856 had advocated the use of chemical agents for the destruction of the infecting agent in typhoid stools. Parkes in 1873 defined a disinfectant as a substance that destroys the specific poison of an infectious disease. Lister's paper in 1867 on the successful treatment of compound fractures by the use of phenol opened up a wide field of investigation, and careful observations were made by Baxter (1875), among others, to determine the range of usefulness of the common disinfectants such as chlorine, potassium permanganate, sulphur dioxide, and phenol. He came to the conclusion that dry heat was probably the most effective of all bactericidal agencies, and emphasized the difficulties of aerial disinfection.

Robert Koch in his classical paper of 1881 with Gaffky and Loeffler drew attention to the particular virtue of saturated steam under pressure, and introduced the first quantitative method for estimating the comparative value of chemical disinfectants. Intensive quantitative work was carried out during the following thirty years by Geppert in Germany, Arrhenius and Madsen in Denmark, and by Chick and Martin, and Rideal and Walker, in this country. No satisfactory method of standardizing chemical disinfectants has yet been devised, and inquiry still proceeds.

The last ten years have witnessed the introduction into medicine of the sulphonamides and of the antibiotics like penicillin and streptomycin, and the attention of bacteriologists is now focused largely on the action of these drugs in the tissues. The older use of disinfectants for the destruction of micro-organisms outside the body is, however, not altogether forgotten; and renewed interest is being taken in the disinfection of the air by ultra-violet light and by various sprays distributed in the form of aerosols or vapours.

Laboratory Investigation of the Infectious Diseases

Time does not permit me to review, even briefly, the epidemiological studies undertaken on the major infectious diseases during the past century, and I must confine myself to a short account of the laboratory investigations made in respect of their prevention and control. Even here I must restrict myself to one or two examples, beginning with diphtheria.

Diphtheria

After the successful isolation in pure culture of the diphtheria bacillus by Loeffler in 1884 there followed an interval of about ten years before the examination of throat swabs for this organism was introduced into routine practice in Great Britain. In 1894 Sims Woodhead, who was director of the laboratories on the Victoria Embankment

belonging to the Conjoint Board of the Royal Colleges, organized a service for the systematic examination of material from diphtheria patients admitted to hospitals of the Metropolitan Asylums Board. In 1895 specimens were examined from 3,648 cases, in 1896 from 4,870 cases; and in 1897 Sims Woodhead was able to take the bacteriological diagnosis of diphtheria as his subject for the first of a series of four Harben Lectures delivered to the Royal Institute of Public Health. Using primary cultivation on Loeffler's medium, followed, when necessary for confirmatory purposes, by growth in broth, he claimed to have found diphtheria bacilli in 95% of clinical cases. What was perhaps more interesting for the epidemiologist was his discovery of these organisms in a number of mild cases of sore throat, not diagnosed clinically as diphtheria, in fully recovered patients during convalescence, and even in healthy contacts. He insisted on keeping convalescents in hospital till they were bacteriologically free from infection, and on isolating child contacts if they were found to be carrying diphtheria bacilli, partly because they might spread the disease and partly because half of these children developed diphtheria themselves in the course of a few days.

Sims Woodhead's work affords an excellent example of the early application of public health bacteriological findings to administrative practice. The routine laboratory diagnosis of diphtheria was begun by Delépine at Manchester in 1894, and by Robertson at St. Helens in 1895. While investigating an outbreak of diphtheria at Cambridge, Cobbett (1901) drew attention to the danger of the nasal carrier.

The discovery by von Behring and Kitasato in 1890 of diphtheria antitoxin, and the introduction by Ehrlich of a method for its exact quantitative estimation, stimulated a demand in this country for preparation of the serum on a large scale. Armand Ruffer in 1894 was the first to make antitoxic serum in this country. The following year Sims Woodhead, with the help of Cartwright Wood, undertook its manufacture for use in the hospitals of the Metropolitan Asylums Board. In 1897 George Dean was appointed to the post of superintendent of the antitoxin department of the British Institute of Preventive Medicine (now the Lister Institute), situated at Sudbury (moved in 1902 to Elstree), and started on a series of investigations that contributed substantially to the present method of producing diphtheria toxin and of immunizing horses against it. In the large outbreak of diphtheria at Cambridge already referred to, Cobbett used antitoxic serum for passive protection of contacts, combined with the isolation of cases and carriers, and succeeded by this means in bringing the infection rapidly under control.

Further progress in the struggle against diphtheria was made when James Ritchie at Oxford described in 1901 a method of modifying toxins by weak acids and alkalis in such a way as to deprive them of their toxicity without destroying their antigenic power. Many years elapsed, however, before this line of investigation was developed, and it was not till the early 'twenties that Glenny and his colleagues in this country and Ramon in France introduced the formol method of detoxication that forms the basis of preparation of our modern diphtheria prophylactics.

The last great weapon in the public health armamentarium against diphtheria is the test introduced by Schick and his colleagues in Vienna in 1913 for ascertaining the susceptibility or immunity of subjects to infection. Though this test has been exploited beyond its capabilities, it provides, when carried out on groups of inoculated children, a simple and reasonably accurate index of the antigenic

potency of diphtheria prophylactic agents and, when carried out on individual adults, a guide to those who need protection and those who do not.

Typhoid Fever

The discovery of the typhoid bacillus by Eberth in 1880, and its isolation in pure culture by Gaffky in 1884, opened the way for the bacteriological diagnosis of enteric fever. The difficulties, however, of culturing this organism from the faeces at a time before enrichment and selective media had been devised were very great, and the application to human serum by Widal and by Grünbaum in 1896 of the agglutination reaction recently discovered by Gruber and Durham afforded a simpler method for distinguishing enteric fever from the numerous other pyrexial diseases with which it could be so readily confused. In this country Dr. D. S. Davies, medical officer of health for Bristol, is credited by Newsholme (1935) as being the first to apply the Widal-Grünbaum test to the investigation of an outbreak of enteric fever and to show its importance in discovering overlooked cases of the disease. Delépine introduced the test into routine practice at Manchester almost immediately after its description, and by 1902 he was able to report that he had used it in 8,000 cases of suspected typhoid fever. Employing a modification of his own, he was satisfied that the error of the test when carried out on sera taken after the first week of illness was not more than 2%.

The interpretation of the results of this test became complicated by the introduction during the South African War of anti-typhoid inoculation, and by the discovery around 1900 of the paratyphoid group of bacilli, in 1903 by Smith and Reagh of flagellar and somatic antigens, in 1920 by Arkwright of the smooth-rough variation, and in 1934 by Felix and Pitt of the Vi antigen. Though the Widal-Grünbaum test is still used in practice, it has been mainly superseded for the diagnosis of enteric fever in inoculated persons by the more reliable cultural methods now available, and its main value probably lies in the detection of the chronic carrier state by means of the modified Vi-agglutination technique.

[The lecturer then summarized the early history of the bacteriological examinations carried out for public health purposes on anthrax, cholera, plague, typhus fever, smallpox, rabies, cerebrospinal fever, and Siberian cattle plague. In respect of the last disease, better known as rinderpest, he drew attention to the discovery by Burdon-Sanderson (1866; see also Lady Burdon-Sanderson, 1911) that the infectious agent in the blood of diseased animals was incapable of passing through an animal membrane, thus providing the first clear-cut laboratory evidence of the existence of filtrable viruses.]

[The second lecture, with a list of references, will appear in our next issue.]

Nearly 1,000 volumes of medical books and periodicals have been distributed through Unesco during the past two months to libraries in eight war-devastated countries. The literature was given by the Army Medical Library of Washington and the Vanderbilt University School of Medicine Library, Nashville, Tennessee. The Army Medical Library in Washington, D.C., acting upon the recommendations of Unesco, distributed to five libraries in Hungary, Poland, and Yugoslavia a total of 635 volumes of scientific periodicals and books in the field of medicine. Following an agreement between Unesco and the American Medical Library Association by which duplicate books and periodicals of American medical libraries will be made available to medical libraries in other countries, a list of duplicates has been received from the Vanderbilt University School of Medicine Library in Nashville. So far 155 volumes have been allocated to ten libraries in Austria, Belgium, China, France, Greece, Hungary, and Poland. A list of the remaining titles for which no specific allocations have been received is being circulated to more than 50 libraries in war-devastated areas.

IDENTIFICATION OF MEDICAL DOCUMENTS

BY

LANCELOT HOGBEN, F.R.S.

MURIEL M. JOHNSTONE

AND

K. W. CROSS

(From the Department of Medical Statistics, University of Birmingham and Birmingham United Hospital)

To fulfil administrative requirements for cross-reference with respect to successive admissions of one and the same person to the same medical institution and to different ones, or to subserve the ends of research involving reference to original records, a system of medical documentation must make provision for identification of individual patients. *Ipso facto* the method of designation must be highly specific in the sense that it excludes the possibility of confusing two individuals. It must also be suitable for transcription by recourse to a numerical code. Otherwise it is not feasible to take advantage of current mechanical methods of sorting and tabulation involving the use of punch-cards.

For the purposes of the punch-card, numerical coding of the birth name is unsatisfactory both because it monopolizes a considerable fraction of space available for other uses and because allocation of requisite columns is highly variable. The complete birth name of an individual may require any number of letters, from a minimum of about seven—e.g., May Hall—to a maximum of about 30. For instance, Henry William Howard Waterhouse would entail the allocation of 28 columns by the alpha system of punching and sorting with respect to a single letter of the alphabet per column.

Frequency of Surnames

Equally important, though too rarely recognized, is the fact that birth names are not highly specific. Farr recognized this long ago, and emphasized its statistical implications in words which are still worthy of citation: "From the indexes of the registers for the year 1853, the probable number of persons in England and Wales bearing each of the 50 most frequent surnames has been computed. . . . The persons by whom these 50 surnames are borne amount to about 3,253,800; nearly one-sixth of the entire population of England and Wales. On an average, it seems, one person in 73 is a Smith, one in 76 a Jones, one in 115 a Williams, one in 148 a Taylor, one in 162 a Davies, and one in 174 a Brown."

In an investigation into the frequency of surnames in a Midland telephone directory we found that the following seven names accounted for 5.6% of 88,351 persons listed: Smith, 1,330 (1.5%); Jones, 965 (1.1%); Williams, 614 (0.70%); Taylor, 550 (0.62%); Green, 520 (0.59%); Brown, 502 (0.57%); Evans, 468 (0.53%).

In one year (1946) the number of new in- and out-patients treated in the Birmingham United Hospital was also about 88,000. With such an intake we might therefore expect the central file of the hospital to accumulate in the course of 10 years records of several thousand Smiths, Joneses, Williamses, Taylors, Greens, Browns, and Evanses. Evidently the task of extracting the records of an individual from a set of documents filed by birth name, or extracting the file number of an individual from a ledger of birth

names, would assume alarming dimensions if there were centralization of medical documents in an administrative region.

In the long run, filing by serial code number without recourse to a ledger of birth names is therefore an administrative necessity. It is also the only practicable system of operating large-scale therapeutic trials or comparable statistical inquiries which entail recourse to detailed information not recorded on the punch-card case summary. Given a punch-card file based on diagnosis, it is possible by present methods of mechanical sorting and tabulation to run off a nominal roll (see Truelove, S. C., and Hogben, L., *Brit. J. soc. Med.*, 1947, 1, 18) of such serial numbers to identify the location of the individual in a central file of complete medical documents with minimum effort.

Three Requirements of Coding

To subserve both ends stated above, a system of serial code numbers must conform to three requirements. It must ensure that: (a) two patients will rarely receive the same serial number; (b) the *fixed* number of ciphers employed do not make excessive demands on the available number of columns of a standard punch-card; and (c) record officers in different institutions will assign without difficulty the same serial number to one and the same patient.

The objective defined by (a) is to ensure the possibility of turning up a patient's records with the utmost dispatch. Since the complete records will necessarily contain information sufficient to distinguish occasional individuals who receive the same serial number, it is not necessary to insist on the absolute specificity of the serial number assigned to him or her. All that matters is to circumscribe the search for a particular document within narrowly defined limits. As regards (b) the allocation of 9 or 10 columns is certainly not excessive, being less than the mean number requisite to code a full birth name as such and on all fours with the new national registration numbers of three letters followed by seven ciphers. The remaining criterion (c) calls for more detailed comment. It carries with it two desiderata: (1) individual ciphers must be referable to personal information which is easily accessible to the record officer and liable to no dubiety with respect to its interpretation; and (2) such information must refer to such characteristics of the individual as do not change in his or her lifetime.

That the choice of such information must be consistent with the fulfilment of the criteria of specificity and of economy of column space imposes further limitations. In particular, it excludes sex as a single unit of classification because the specification of the two sexes leaves vacant eight out of the ten rows of a column assigned to it. It excludes birth rank for a less obvious reason. Though it would be easy to assign the birth rank to a single column by reserving the last row for tenth or later live births in the patient's sibship, such an arrangement would not be economical inasmuch as high-grade specificity presumes *equipartition of statistical frequency to each of a set of exclusive classes*. As it happens, more than one-third of all children are firstborn. Hence the probability that two individuals taken from a population at random will have the same birth rank is far greater than 0.1, which is the minimum attainable for a single column of 10 rows.

The desideratum specified by (1) above excludes numerical coding of blood groups because this would necessitate the performance of a laboratory test, and of birthplace because this would entail recourse to a voluminous gazetteer. Birthplace is also exceptionable on account of (2), because topographical landmarks often change in the lifetime of an

individual consequent upon redistribution of local government responsibilities. For both reasons we may also dismiss fingerprints, since their interpretation is too specialized an art, and the loss of a limb destroys the possibility of subsequent identification. Aside from this, fingerprints have associations which do not find favour with a considerable body of patients. It goes without saying that eye colour, marital status, religion, and occupation are each inconsistent with (2) above, though eminently appropriate if (1) were the only prerequisite.

Considerations stated above are largely relevant to any satisfactory method of serial-number specification attached to a birth certificate or analogous personal document for purposes other than the one which is the theme of this discussion. Admittedly, a quite arbitrary national identity number assigned at birth would dispense with the need for an *ad hoc* examination of the issue in this context; but we have as yet no guarantee that the wartime system of national identity numbers will survive, and any proposal for its permanent adoption would encounter a formidable body of public opinion suspicious of regimentation. In any case, the present system is for several reasons unsatisfactory as it stands. One is that individuals on leaving the armed Services at present receive an identity number which is not the one they had before enlistment. Another, which will be more evident at a later stage, is that it lacks the merit of making explicit information, which has otherwise to be coded separately for general use.

Six-cipher Code

The principle implicit in the last statement offers an opportunity for illustrating how it is possible to make use of a run of ciphers embodying information which is at the same time (a) immediately accessible to a recording officer, (b) invariant with respect to the lifetime of the individual, and (c) useful for a wide variety of statistical purposes. A hospital record must give the age of the patient, and the six ciphers which can specify this suffice to make the datum explicit on any document which bears a serial number in which they occupy a *fixed* position. For instance, the birth date of one of us is Dec. 9, 1895, that of another Aug. 16, 1925. Transcribed direct by day, month, and year without specification of the century, as in general irrelevant, these would be respectively 091295 and 160825. Clearly the act of assigning such a label to an individual involves no issue of regimentation, since no one except the record officer and hospital staff with access to the confidential documents involved would need to know the patient's number. Nor would the patient need to know it. Equally clearly, record officers in different institutions would fill in the same run of ciphers assigned to the same fixed position in the serial number in the same way. These six digits do not necessarily require six columns on a punch-card. Since there are only 12 calendar months, it would be possible to record the two ciphers standing for the month on one column by recourse to the X and Y pigeon-holes.

We have now to ask what level of specificity a six-cipher sequence based on the birth date would guarantee. A convenient measure is the chance that two individuals taken at random will have the same cipher sequence. The chance that any individual will have the same birthday as another is of the order of 1 in 360. In Britain we may put the chance that two individuals taken at random will be of the same age—i.e., that they will have been born in the same year—at about 1 in 50. Thus the number of live individuals in England and Wales with one and the same six-cipher birth-date sequence should be about 2,000.

Ten-cipher Code

By employing four additional ciphers we can greatly reduce the possibility of confusion: how greatly depends on partition of information employed to assure approximately equal relevance to each of the 10,000 compartments which four ten-row columns accommodate. Whether such partition is more or less easy is an empirical issue. Accordingly we have made an analysis of the initial run of letters in 88,000 surnames of a Midland telephone directory to explore the possibility of grouping such initials in 100 blocks of equal frequency with a two-figure code for each block—e.g.:

AA—AK	... 00	BAA—BAJ	... 04
AL	... 01	BAK—BAQ	... 05
AM—AR	... 02	BAR	... 06

If p_x is the proportion of surnames assignable to the x th block we may define a convenient coefficient of specificity (C_x) for the two relevant columns in accordance with the following definition:

$$C_x = \frac{x - 99}{\sum P_x^2} \quad x = 0$$

As against the theoretically realizable C_x ($=0.01$) a straightforward code designed as stated on the basis of information supplied by an 88,000 sample of surnames yielded the highly gratifying figure 0.01073. This result does not justify us in offering for national use the specimen surname initial code (C) printed below, since the best code for the whole nation should be based on a national sample more representative of the population than the contents of a regional telephone directory. None the less, the Midland region is fairly representative of the country as a whole, and we may therefore assert with confidence that a foolproof two-cipher surname code devised for use on the *same pattern* would prove to have a C_x not far off 0.01. The only name in our sample which requires a block to itself is Smith (1.5%). If Smiths are more common in the country as a whole than they are in the Midland region it will be possible to deal with them as we deal below with first names such as William.

To make good use of two additional ciphers we have examined the possibility of coding first names on a principle which makes the sex of the individual explicit in the first digit. For this purpose we have prepared a frequency distribution of 3,000 *male* first names and 4,000 *female* first names in our hospital register. The result shows that certain first names have a relative frequency much higher than 0.01. Where this is so it is possible to ensure approximate equipartition of information by recourse to live-birth rank specification—e.g.:

						Code No.
Francis	15
Frank	15
Frederick, Birth rank	1	16
" "	> 1	17
F (excluding above)	14

By assigning the two-cipher sequence 00–49 (Code A) to males and 50–99 (Code B) to females we are able to distribute first names with a C_x equal to 0.0103. As it stands we do not claim that such a code is ideal for the nation, or even for the Midland region. We are content to assert that Codes A and B provide a pattern for a more satisfactory attempt in conformity with the requirements stated above.

The complete proposal which emerges from the foregoing analysis of surnames and first names undertaken to

One minor issue which calls for comment is the occurrence of first names, such as Evelyn or Francis, which are not distinctively male or female. The proposed system takes this into account by prescribing a separate code A for the

individual treated in different institutions and relies on a name-and-address ledger for identification of the numerical locus of an individual in a large-scale file.

Conclusion

Our submission is that a code based on the same pattern as the Birmingham system, though not necessarily satisfactory in detail for the nation as a whole, would ensure:

(a) That a record officer in Beachy Head would assign to a commercial traveller treated for fracture in the Birmingham Accident Hospital and subsequently re-examined in Bedford the same serial number, which would identify his position in the record file of the Birmingham or Bedford institution; and he or she would hence be able to obtain therefrom information relevant to treatment with minimum effort and delay.

(b) That all records of one and the same individual successively admitted to one and the same institution either as an in-patient or as an out-patient would be available for research in one and the same niche in its file of medical documents without recourse to a name-address admission-and-discharge register.

first two ciphers if the individual is a male in contradistinction to Code B for females. Thus Evelyn, a male, being known as such, is "E (excluding above) 14" in Code A. Evelyn, a female, is "Evelyn 67" in Code B.

In the best of possible worlds clerical errors must occasionally occur ; but clerical errors in transcription of a code such as this could be open to supervisory inspection at source by recourse to a standard admission card, explicitly recording a woman's maiden name and the birth date of an individual irrespective of sex. As a safeguard against erroneous statement on the part of the patient or the relatives of the patient it would be easy to specify an appropriate *check question* routine for the record officer engaged in filling in the standard admission slip or card. The most generous allowance for occasional errors of this sort can have little weight if the alternative is a system which necessarily assigns different serial numbers to the same

A delegation from Charing Cross Hospital visited five hospitals in Europe to study methods of hospital design and planning. The five hospitals were the Neue Bürgerspital in Basle; the Polyclinic in Zurich; the Kinderspital in Zurich; the Beaugnon Hospital in Paris; and the New Southern Hospital in Stockholm. This visit was arranged by the King Edward's Hospital Fund for London, and the long report which was subsequently prepared by Sir John Stewart-Wallace, Mr. Norman C. Lake, Dr. H. W. C. Vines, and Dr. A. Doyne Bell was reviewed in the *Journal* of Nov. 1, 1947 (p. 704). The report has now been published and copies are available, price 1s., from the Honorary Secretaries of the Fund at 10, Old Jewry, London, E.C.2.

TREATMENT OF HYPERIDROSIS

BY

H. A. HAXTON, M.D., Ch.M., B.Sc., F.R.C.S.

(From the Neurovascular Clinic, Manchester Royal Infirmary)

The condition of essential hyperidrosis is seen in those parts of the body which are affected by mental or emotional sweating, as opposed to thermoregulatory sweating. These are the palms of the hands, the soles of the feet, all the digits, and to a smaller extent the head and face.

Hyperidrosis is met with in varying degrees of severity, from a slight excess of normal sweat-gland activity to a condition in which sweat drips from the skin continuously during waking hours, often leading to considerable embarrassment and to interference with activities, even to the extent of making the patient's usual work impossible. The milder types may be controlled by formalin foot and hand baths, with some risk of a dermatitis developing, or by painting with a solution of alum, but such treatment is of no avail in the severe degrees. X-ray treatment must be pushed to a dangerous limit in order to damage the secreting glands in the skin, and there is grave danger of a chronic dermatitis, or even skin necrosis, resulting. On the other hand, section of the sympathetic pathway to the affected part provides a safe and certain cure. This procedure cuts off all sudomotor activity and results in an immediate and profound dryness of the skin in the distribution of the divided fibres.

Previous reports (Adson, Craig, and Brown, 1935; Telford, 1938; White, 1939) have shown that hyperidrosis can be abolished by such operations, but the follow-up periods were short. (Out of five cases in each of the series by Adson *et al.* and by White only one was seen more than twelve months after operation, and out of three cases reported by Telford only one had been followed up for a prolonged period.) In view of the fact that regeneration of divided sympathetic fibres occurs in animals (Langley, 1894, 1897; Lee, 1929; Grimson, 1946) and that there is strong evidence that it takes place in man (Simmons and Sheehan, 1939; Haxton, 1947) a longer follow-up is necessary to evaluate the permanency of the cure.

The present study includes the follow-up of several cases for much longer periods. In all, 12 cases of severe hyperidrosis have been treated by sympathetic section in this clinic over the past 15 years, and have been followed up with great care. Operation was considered to be justified in cases in which the sweating was a severe nuisance or an embarrassment, or when it actually interfered with the patient's occupation.

Operations

Three operations have been used. For hyperidrosis of the face and neck section of the sympathetic chain has been carried out above the middle cervical ganglion, with dislocation of the upper end by drawing it through the sternomastoid muscle. The incision employed has been in the line of the skin folds of the neck, centred on the posterior border of the sternomastoid muscle at the midpoint of its length. The muscle is retracted forwards and the sympathetic chain is found lying on the longus cervicis muscle when the carotid sheath and its contents are retracted medially. It is worth recording that a partial result has been seen after the undoubted division of a sympathetic filament in this region, and on second exposure a further filament was found, situated more medially, division of which gave a completely satisfactory result. Therefore the region posterior to the common carotid artery and

internal jugular vein must be carefully searched for reduplication of the cervical sympathetic chain.

For hyperidrosis in the hands the operation employed is the Telford (1935) procedure of thoracic sympathectomy below the third thoracic ganglion, with dislocation of the upper cut end after section of the rami to the second and third thoracic ganglia. This operation, carried out by the anterior approach, is a relatively easy one to the experienced hand, and the convalescence is rapid and free from pain. It has the advantage over cervico-thoracic ganglionectomy that the disfiguring Horner syndrome is entirely avoided by leaving intact the first thoracic white ramus communicans.

Lumbar sympathectomy is now done through separate oblique muscle cutting or splitting incisions in the flanks, with extraperitoneal approach to the sympathetic chain. From 3 to 6 cm. of each chain, centred on the third lumbar vertebra, are removed. Both sides are done at one session, under spinal analgesia, and convalescence has been singularly uneventful.

Results.—The immediate result has been a complete anidrosis in the zone of sympathetic denervation, the extremity being quite dry. The inevitable vasodilatation does not appear to have caused any trouble. For practical purposes the cure seems to be permanent, since in no case has hyperidrosis returned, the most that has been noticed in the way of sweating being a slight moistness of the hands when warm. The patients have all been most grateful for the relief obtained in this uncomfortable and embarrassing condition.

Case Reports

Case 1.—A meter inspector aged 38 noticed excessive sweating of the feet one year before admission. The condition was so bad that in the course of his daily round of 12 to 14 miles he had to empty his shoes of water and wring out his socks six times. His feet became macerated, and he was laid up for nine months, receiving treatment in various hospitals for mycotic infection with no benefit. Bilateral lumbar sympathectomy was carried out in January, 1932, by Prof. Telford, and the feet were dry and healed in three weeks. When last seen, in October, 1941, he remained free from trouble and the feet were quite dry.

Case 2.—A female cotton-packer aged 16 was troubled with excessive sweating of the hands and feet, with blistering of the hands in hot weather which prevented her from working. The Telford operation was carried out on both sides in September, 1937, and was followed by complete dryness of the hands. They became slightly moist two years later, and have remained so without getting any worse. She has had marked gustatory sweating of the forehead and face since 1942, six years after the operations. The chief stimulant is cheese, and now the thought of this brings on the sweating. On Oct. 20, 1945, the whole body was heated strongly in a radiant-heat apparatus. After remaining dry for ten minutes the hands suddenly began to sweat profusely. A trace of perspiration was seen on the forehead. On March 11, 1947, paravertebral block of the sympathetic chains in the upper thorax with 2% procaine resulted in a great increase in skin temperature and electrical resistance in the hands but no sensor, or motor disturbance.

Case 3.—A man aged 22 had profuse sweating of the hand for three months which resulted in excoriation of the skin on the pads of his fingers. He had to give up his work in a paper mill because the sweat spoilt the materials which he handled. In November, 1937, the Telford operation was carried out on both sides, and was followed by immediate and complete dryness of the hands. He was last seen two years later, at which time he remained completely cured.

Case 4.—A male cleaner aged 48 had a twelve-month history of hyperidrosis in the hands, with swelling at cheirpompophylx which made them useless for work. On April 30, 1938, he had a Telford operation on the right side following which the right hand has remained warm and dry

he left hand has also improved, though it still sweats. No normal sweating of the face has been noticed. At a test on July 10, 1945, both hands were very warm, the right being dry and the left sweating. Measurement of the electrical conductivity of the skin of the digits was made before and after block of the right ulnar nerve with 2% procaine, and after strong heating of the body. The method is described elsewhere (Axton, 1947). The test shows that sudomotor activity was present in the right upper limb seven years after sympathetic section, but in spite of this the clinical result is good and the hyperidrosis remains cured.

NOTE.—The sign + indicates the midline of the ring finger.

Case 5.—A lad aged 16 had severe hyperidrosis for 10 years. It was so bad that when he was reading a book the sweat used to run from his hands down to the elbows and drip from there on to his trousers. He could not write without a double sheet of blotting-paper under his hand to catch the drips. He was unable to go dancing because of the trouble. In January, 1939, he had a Telford operation on both sides, with immediate and complete relief from the hyperidrosis. He has remained cured, though when very warm he has noticed slight sweating of both hands since the beginning of 1945. In the last three years he has noticed gustatory sweating on the face and forehead on eating sour things, although these areas have remained free from sweating in response to heat.

Case 6.—A female domestic servant aged 26 had excessive sweating of the hands for three years. She was also troubled with Raynaud's disease in the hands, which was progressing in severity. In June, 1939, a Telford operation was performed on both sides. The immediate result was excellent, both for the hyperidrosis and for the Raynaud spasms. When seen in February, 1941, however, the latter had returned and the condition was little better than before operation, although the hands remained dry.

Case 7.—A female warehouse assistant aged 18 had hyperidrosis of the hands and feet for three years, severe enough to interfere with her work. She had a Telford operation on the right side in October, 1939, and on the left side in January, 1940. The hands have remained completely dry since then, but within two months of operation she noticed gustatory sweating on taking cheese or sweetmeats, and particularly on eating chocolate. This condition persisted unchanged when she was last contacted in May, 1947.

Case 8.—A female school attendance officer aged 35 had a history of cold and damp hands and feet for as long as she could remember. The sweating of the feet was so bad that it caused her stockings to rot. She was troubled with Raynaud attacks in the hands in cold weather, and suffered from severe chilblains on the hands and feet all the winter. When examined the hands and feet were cold and quite wet with perspiration. In September, 1943, a bilateral lumbar sympathectomy was carried out, and in October, 1943, Telford operations were done on both sides. Since then the hands and feet have remained dry, but the fingers are again red and painful in cold weather. She noticed gustatory sweating of the face on taking vinegar six weeks after the operations. The hyperidrosis, then, has been cured by operation, but the sensitivity to cold has been only partially relieved.

Case 9.—A housewife aged 36 had a six-months history of hyperidrosis of the left side of the face when warm or embarrassed. The sweating extended to the lower border of the mandible and was accompanied by flushing and tingling of the skin. For the same period she had a marked rhinorrhoea confined to the left side, for which she had two nasal operations without benefit. In July, 1945, the left cervical sympathetic chain was sectioned above the middle cervical ganglion. The result was complete anidrosis of the left side of the face and

neck, and cessation of the rhinorrhoea. The cure remained complete when she was seen in May, 1947. She had, of course, pronounced Horner's syndrome, but this is well concealed by the stroop cocoave lenses which she normally wears.

Case 10.—A man aged 22 had suffered from hyperidrosis, mainly of the face, when at work, at the cinema, or after hot meals, and the condition was causing him considerable worry and embarrassment. In June, 1946, a bilateral section of the cervical sympathetic chains was carried out above the middle cervical ganglion. The immediate result was complete dryness of the face and bilateral Horner's syndrome. He was tested three months later by strong radiant heat to the body and limbs, when profuse sweating was induced all over, except for the head and neck down to the level of the second rib, which remained quite dry. When he was last examined, in May, 1947, the cure remained complete.

Case 11.—A machinist aged 22 had had excessive perspiration of the hands and feet for as long as she could remember. The sweat dripped from her fingers at times. She had also noticed slight sweating of the face on eating sauce. In August, 1946, she had a Telford operation on both sides, and when tested by strong radiant heat several weeks later she sweated profusely up to the third intercostal space, and remained dry above that level, including the upper limbs, head, and neck. When seen on May 15, 1947, the cure remained complete in the hands, and the feet still sweated excessively. Her slight gustatory sweating remained as before operation.

Case 12.—A coach painter aged 20 was troubled with pronounced sweating and flushing in a small area on the ulnar border of the left forearm just above the wrist. The syndrome came in attacks, lasting two to nine hours, when he was nervous or making a mental or physical effort. This condition had been present for four years. On March 11, 1947, he had a left thoracic sympathectomy, with immediate cessation of the hyperidrosis, and he has had no further trouble with it since.

Discussion

Five of these cases have been followed up for more than seven years after operation (average 8.6 years), and in none of them has the hyperidrosis returned. It can therefore be claimed that a prolonged and probably permanent cure is effected by this treatment. Two of the cases reported slight sweating of the hands two and six years after operation, and this has continued, unchanged in degree, up to the time of writing. In one of these cases this slight moistness of the hands was abolished by a paravertebral block of the sympathetic chains in the upper thorax, and this, along with the accompanying rise in skin temperature, indicates that regeneration of sympathetic fibres has taken place. In spite of this, however, there is no indication that more than a very slight degree of sweating returns, and from a practical standpoint the patients remain cured.

The causes of hyperidrosis can be divided into those known and those unknown. Of the former, irritative lesions affecting the sympathetic pathways in the spinal cord or at any point between it and the periphery have been associated with hyperidrosis. Syringomyelia, for example, may be a cause of excessive sweating of the face (Wilson, 1936). Pressure on the fasciculus of sympathetic fibres in the lower trunk of the brachial plexus (Telford and Stopford, 1931) by a cervical rib is an uncommon cause of hyperidrosis, usually affecting one hand only (Telford, 1942). In hyperidrosis of the hands, therefore, a radiograph should be taken to exclude this possible cause. This type is cured at once by removal of the cervical rib, or in some cases by division of a tense fibrous band in the scalenus medius muscle.

For most of the cases no definite cause can be found, and the explanation remains obscure. Psychic disturbances have been blamed (Cobb, 1938), but the development of the condition before the age of 10, as in two of the cases reported here, is against this theory, as is the very localized distribution of the hyperidrosis in some cases—for example,

Case 12. The theory of Leslie-Roberts (1934) that the condition is due to abnormal function of mesenchymal cells in the dermis is hard to reconcile with the spontaneous development of the trouble in a localized area of skin, and with the finding that the hyperidrosis does not return although regeneration of the sympathetic fibres takes place. If, as he believes, these fibres function as a trigger mechanism for starting the excessive sweating, then any return of sympathetic activity should provoke the full response, since the sweat glands do not undergo degeneration after sympathetic denervation (Adson *et al.*, 1935). Evidence of sympathetic overactivity is present in some cases of hyperidrosis in the form of excessive vasospasm, resulting in acrocyanosis or in attacks of the Raynaud phenomenon. Most cases are, however, free from these manifestations, and the disturbance is most likely due to excessive activity in some localized part of a sudomotor centre, probably in the hypothalamus.

No fewer than four of the patients whose cases are reported above had observed that after the Telford operation of thoracic sympathectomy the eating of food was accompanied by sweating of the forehead and face. The foods which provoked the strongest reaction differed in these cases, being cheese in one, chocolate in another, and vinegar in the third and fourth. The latent period between operation and the first detection of the sweating varied between six weeks and six years, and in three cases the condition has persisted unchanged for three to five years. The patients state characteristically that on eating the appropriate food, usually a strongly flavoured food, they feel a tingling or warm sensation in the face or scalp, accompanied by flushing of the face, and in a short time beads of sweat appear, mainly on the forehead but also in the circumoral region. The condition is not severe enough to cause the patient much trouble or embarrassment.

The gustatory sweating has not previously been reported as a complication of upper-limb sympathectomy, although its occurrence after superior cervical ganglionectomy has been noted. Conflicting theories have been advanced in explanation, and indeed it is difficult to account for sweating occurring after the sudomotor pathways have been divided. (Thermoregulatory sweating on the head and face is almost or completely abolished by preganglionic operations for the upper limb.) This fascinating phenomenon is the subject of a special study which will be reported later.

Summary

A study of 12 cases of hyperidrosis treated by sympathetic section, five of them followed for more than seven years, has shown that the operation affords a prolonged and probably permanent cure for this uncomfortable and sometimes disabling condition.

Gustatory sweating of the head and face is a frequent development after the upper-limb operations.

I wish to express my grateful thanks to Prof. Telford for his stimulating interest in this work, and for permission to report on his cases.

IMMEDIATE PROSTATECTOMY FOR RETENTION OF URINE

BY

G. A. BAGOT WALTERS, F.R.C.S.Ed.
Honorary Surgeon, County Hospital, Lincoln

In recent times so many different procedures have been advocated for dealing with cases of benign prostatic hypertrophy that it is becoming increasingly difficult to estimate the value of new methods of treatment. This difficulty has been amply shown by the conflicting views put forward at discussions which took place in 1946 at the Medical Society of London and at the Annual Meeting of the British Association of Urological Surgeons. It seems important, therefore, for surgeons employing new methods to publish their results so that their experiences may be shared by others, and this reason prompts me to place on record a small series of cases.

On going through my case records some years ago I was shocked at the bad results they revealed: in spite of refusing radical operation to a big proportion of cases, the mortality rate was appallingly high. Among 27 cases of permanent suprapubic cystotomy there were 6 deaths (22%), and the rate for prostatectomies was over 15% (Table I, Series I). Unfortunately, this does not appear to

TABLE I.—Results of Treatment in Cases of Benign Prostatic Hypertrophy

	No. of Cases	No. of Deaths	Mortality Rate
Series I.—82 cases: 52 (63%) submitted to radical operation			
Suprapubic prostatectomy, I or II stage ..	38	7	15.4%
Perurethral prostatectomy (McCarthy) ..	14	1	
Permanent suprapubic cystotomy ..	27	6	22.2%
No operation ..	3	2	66.6%
Series II.—132 cases: 106 (80%) submitted to radical operation			
Suprapubic prostatectomy, I or II stage ..	11	1	8.5%
Perurethral prostatectomy (cold punch) ..	95	8	
Permanent suprapubic cystotomy ..	23	6	26%
No operation ..	3	1	33.3%

be an isolated experience; for instance, Harbord (1943) records 15% for 94 cases of suprapubic prostatectomy. Owing to these depressing figures my attention was directed to the perurethral operation with the Thompson cold punch, and this method was used almost exclusively for the next series of over 100 cases (Table I, Series II). Though this resulted in diminished mortality, a big drop in the number of patients treated by permanent suprapubic cystotomy, and a welcome rise in the operation rate, the method was not entirely satisfactory. A very high degree of technical ability, which can be acquired only after considerable experience, is required for the successful use of the cold punch, and the need for intensive after-care puts a big strain on the staff where cases have to be nursed in the general surgical wards of a busy hospital. Furthermore, there is a definite recurrence rate (though admittedly dependent on the skill of the individual surgeon); haemorrhage is sometimes very difficult to control, and various complications such as extravasation or urethral damage may arise. Hoffman and Werthammer (1946) even go so far as to state that "statistics show that approximately one out of three cases of transurethral resection of the prostate gland develops complications."

For some considerable time the belief has been gaining ground that gradual decompression is not necessary for treatment of cases of urinary retention. Ten years ago Creevy (1938) concluded that "gradual decompression should be abandoned." He reached this conclusion after treating two groups of 120 cases with more than 500 ml.

of residual urine—one series by gradual decompression and the other without regard to the rate of emptying—the mortality of each group being almost identical. More recently other surgeons have supported the principle of early operation; for instance, D. K. Rose (1945) stated: "Gradual decompression is omitted in fact and in principle, because as a normal or particularly a gradually obstructed bladder empties, its pressure increases. . . . The patient is operated on from the street in better health than from the 'sulfa, catheter, anticipatory, lost appetite, and lessened physiological tone' bed." Moreover, preliminary drainage by catheter or suprapubic tube carries a high mortality, mainly from the resulting infection.

Skyrme Rees (1947), in recording 643 cases of benign prostatic enlargement from Birmingham, found 18 patients had died during gradual decompression of the bladder by catheter, and of 106 cases treated by suprapubic drainage 30 died in hospital (28%). Further, from the results of 64 post-mortem examinations he concluded "by far the commonest cause of death after surgical treatment was severe sepsis in the urinary tract." In addition there are other disadvantages of preliminary drainage. For instance, Wardill (1946) is reported as saying: "I do not believe in permanent suprapubic drainage. If a tube were put into the bladder it might be found that it did not in any way improve the patient's condition. The same applies to catheter drainage for any length of time. I believe that often the enlarged prostate pushed its way up into the bladder and that the ureters were actually obstructed by the prostate itself." My own experience has proved that a permanent suprapubic tube is extremely unsatisfactory for the type of patient predominant in my clinic, most of whom come from a sparsely populated rural area.*

Immediate Prostatectomy

In this country it was Wilson Hey (1945) who first used immediate operation for a large series of cases, and he showed a mortality rate of only 6% for his "aseptic operation." Later figures were even better—24 deaths in 565 consecutive cases—4.3% (Hey, 1946). As Hey's procedure abolished the use of a suprapubic tube, gave a short convalescence, and required a minimum of post-operative care, it seemed a better operation for routine use than the complicated technique of the cold punch. The method of "immediate prostatectomy" was therefore adopted for all cases in my next series irrespective of their condition, though a perurethral operation was still used where it appeared specially indicated, such as for dealing with small fibrous glands. This term is used in preference to "aseptic prostatectomy" because, though asepsis is of paramount importance and an ideal to be aimed at, in

*Since this paper was completed I have successfully removed the prostate from a patient who had been treated by permanent drainage and was in such a miserable condition that he had twice been in another hospital after attempts at suicide.

practice it is very difficult of attainment for various reasons. Thus a high proportion of my cases had been catheterized before admission, a few were referred after they had already been treated by either an indwelling catheter or a suprapubic tube, and, lastly, where the diagnosis was in doubt some cases were cystoscoped immediately before operation.

More recently Millin's (1945) retropubic operation has been performed; in my hands it gives better control of bleeding and there is much less chance of leakage from the suture line in infected cases. At the same time the principles laid down by Hey have been adhered to and immediate operation is practised wherever possible, cases of acute retention being done as emergencies where practicable, or else a suprapubic needle is inserted for a few hours until operation can be undertaken. The actual operative technique employed differs little from Millin's original description, but a V-shaped wedge is excised from the posterior margin of the prostatic rim in every case. Spinal anaesthesia with heavy "nupercaine" by the volumetric method (Hunter, 1945) is employed as a routine, but in some of the worst cases a rectus muscle block and cyclopropane have been used with satisfactory results.

Table II is a complete record of cases from the first immediate prostatectomy, for unless every case is recorded

TABLE II.—Results of Treatment by Immediate Prostatectomy
Series III.—141 cases: 133 (95%) submitted to radical operation

	No. of Cases	No. of Deaths	Mortality Rate
Suprapubic prostatectomy (Hey or Millin) ..	115	9	7.2%
Perurethral prostatectomy (cold punch) ..	23	1	
Permanent suprapubic cystostomy ..	0	—	100%
No operation* ..	3	3	
Cases of acute retention ..	70	4	5.7%
Cases of chronic retention with overflow ..	27	3	11.1%
Cases of prostatic syndrome ..	41	3	7.3%

* Aged 76: admitted with acute retention and cardiac failure; died the same day. Aged 76: admitted with acute retention and cerebral thrombosis; died the 6th day. Aged 71: admitted with chronic retention, uraemia, pyelonephritis, and bronchitis; died the following day.

any series of figures is without much value. It is difficult to define "chronic" retention, particularly when no catheter is passed before operation to determine the amount of residual urine: I have therefore classed as chronic retention only those cases which showed a distended bladder with overflow incontinence. All cases not classed as acute or chronic retention have been grouped together under the heading "prostatic syndrome," and they include cases referred after a previous suprapubic cystostomy.

Deaths

Detailed examination of Table III shows that of the four deaths out of 70 cases of acute retention two were not treated by immediate operation. Case 2 was admitted with

TABLE III.—Details of Deaths in Series III

Case No.	Age	Condition on Admission	Blood Urea mg./100 ml.	Pre-operative Treatment	Type of Operation	Time and Cause of Death
1	78	Acute retention B.P. 260/140	114	Nil	Hey	9th day. Pneumonia and uraemia
2	73	Acute retention; pneumonia	46	10 days cath. and for chest	Millin	6th day. Pneumonia and cardiac failure
3	76	Acute retention; cardiac failure	26	16 days cath. and for heart		8th day. Cardiac failure. Necropsy also showed carcinoma of stomach
4	82	Acute retention	26	Catheterized before admission	Hey	8th day. Cardiac failure and senility
5	67	Chronic retention; oedema of legs	133	Nil		8th day. Uraemia and myocarditis; post-op. clot retention
6	77	Chronic retention	—	5 weeks in bed at home	Millin	5th day. Bronchopneumonia
7	73	Chronic retention; oedema of legs	266	Nil		19th day. Cardio-renal failure after blood transfusion
8	61	Prostatic syndrome	39	Nil	Hey	21st day. Septicaemia from wound sepsis—cross-infection in ward
9	53	Senile: permanent suprapubic tube	40	Bladder wash-outs and for heart	Punch	10th day. Cardiac failure and senility
10	79	" "	37	Bladder wash-outs		19th day. Cardiac failure 2 days after closure of suprapubic sinus under local anaesthesia

severe bronchitis, and was treated conservatively till the chest was better. Unfortunately he had a relapse about 12 days after operation, and finally died on the 63rd day. Case 3 was admitted with cardiac failure and auricular fibrillation. I therefore attempted to tide him over with catheterization, but when this had failed to relieve him and the cardiac condition had improved operation was undertaken. Possibly these patients might have survived had they been treated with simple suprapubic drainage. In neither instance was there evidence of much renal damage, and therefore not such strong contraindication to tube drainage and its associated sepsis.

Among the cases of overflow retention there were three deaths out of 27 operations. Case 5 had a bad setback with post-operative clot retention, and this was a material factor contributing towards his death. Case 6 had been kept in bed for five weeks before I saw him, and this fact probably contributed to the onset of the chest condition to which he succumbed. Case 7 was a bitter disappointment: in spite of an initial blood urea of 266 mg., he made good but slow progress till the 19th day. At this stage it was decided to expedite his recovery with a blood transfusion. While this was in progress he had a rigor followed by left-sided facial paralysis, and died shortly afterwards. Necropsy showed a poor myocardium, and Dr. H. R. Mavor, the pathologist, considered death was due to transfusion reaction.

Of the group classified as "prostatic syndrome," Case 8, a fit man of 61, developed mild wound sepsis, but unfortunately at that time there was an outbreak of streptococcal infection in the ward, and he died on the 21st day from cross-infection: blood culture showed a haemolytic streptococcus. Cases 9 and 10 both insisted on having something further done as they were so miserable with their suprapubic tubes: in each instance they were advised against further operation. Case 9 had refused to have his tube put back when it was taken out by his doctor for routine replacement, and was in a miserable condition owing to a suprapubic fistula. Case 10 always had a low-grade infection around his tube, and this resulted in an unpleasant eczematous condition of the genitalia.

Commentary

Admittedly it is difficult to draw conclusions from a small series of cases, and owing to the advent of new sulphonamides and penicillin the three series quoted here are not strictly comparable. However, it is submitted that the figures shown give strong support to the theories put forward by Wilson Hey (1945), who maintains that "post-operative uraemia is due to infection and is encouraged by any method of slow decompression, open drainage, or instrumentation." Certainly it has been my experience that cases catheterized before admission were far more apt to give trouble during their convalescence.

If only selected cases are submitted to radical operation a low mortality rate can be obtained, but emphasis is laid on the fact that *all* my cases are included in this report, and some were extremely sick patients and really deplorable operative risks.

The benefits of immediate prostatectomy for the patient with retention of urine are very great, for he is spared prolonged and sometimes painful pre-operative treatment and a long illness. Some notice must also be taken of the economic factors involved, as the rapid recovery of patients is most necessary at the present time, when there is such a shortage of hospital beds.

Attention to details in treatment is of paramount importance, for even a comparatively trivial setback, such as a blocked catheter, may have serious consequences in

elderly and decrepit patients. All cases get out of bed the day after operation, and to this may be attributed the low incidence of chest complications. The majority go home in good condition about the 12th to 16th day.

Summary

A consecutive series of 141 cases of benign prostatic hypertrophy is recorded; 138 were submitted to radical operation.

Except on very rare occasions, drainage before operation, whether by catheter or suprapubic tube, is not considered necessary or desirable.

There were 97 cases of retention of urine which, wherever feasible, were treated by immediate prostatectomy: 7 (7.2%) died; 70 were operated on for acute retention, with 4 (5.7%) deaths.

As many cases were admitted in very poor condition, the results shown are considered satisfactory. It seems that the method of immediate prostatectomy is well worthy of an extended trial.

I am indebted to Dr. J. Clutton Brock, who was responsible for most of the anaesthetics, and to my house-surgeon, Mr. P. F. Philip, for his help in compiling statistics and for doing some of the emergency operations on my behalf.

SOME SIMPLE OBSERVATIONS ON TRANSFUSION REACTIONS

BY

JOHN WALLACE, M.B., B.Sc.Edin.

*West of Scotland Blood Transfusion Service; Late Specialist in
Blood Transfusion and Resuscitation, R.A.M.C.*

AND

R. D. RICHARDS, M.B., B.Ch., B.Sc.Wales, F.R.C.S.Eng

*Surgical Registrar, Morriston Emergency Hospital;
Late Surgical Specialist, R.A.M.C.*

During the training of several hundred transfusion orderlies it was possible to make some simple observations on transfusion reactions. It was essential that these orderlies should be able to perform venepuncture and to carry out transfusions themselves lest at any time under active service conditions the medical officer was not available. In order to give them the opportunity of acquiring the technique of inserting needles into veins, the majority of the orderlies volunteered to undergo venesection, and subsequent reinfusion by their colleagues, under the supervision of one of the instructors. The volunteers were each venesected to the extent of 440 ml. of blood, and their own citrated blood was reinfused. In this way 324 collections and reinfusions of blood were performed, and in addition 56 infusions of glucose-saline, each of 540 ml., were given. The reactions observed are described.

Febrile Reactions

Oral temperatures were recorded by leaving a thermometer *in situ* for at least three minutes, and records were taken before and at hourly intervals for four hours after

infusions. Out of a total of 324 infusions of blood a rise of temperature was observed on nine occasions, an incidence of 2.8%. Using the classification of Riddell (1939), seven of these reactions were Grade II (2.2%) and two were Grade III (0.6%). It was possible to state the probable cause of these reactions in all but one case.

Investigation of the first reaction showed that a new orderly had inadvertently taken a set from the non-sterile pile unknown to the supervising medical officer. This was a Grade II reaction, and that it was not more severe was probably explained by the fact that the set had been recently assembled from carefully washed components, and by the fact that the blood was fresh and therefore still retained some bacteriostatic properties.

The second febrile reaction occurred in a volunteer reinfused with his blood, which had been collected into a sample of sodium citrate free from moulds but containing numerous small particles such as are not infrequently present in bottles of crystalloid transfusion fluids. A Grade III reaction ensued, but an interesting feature of this case was that the onset of the rigor was delayed for some two hours after the end of the transfusion.

For the third observed febrile reaction no explanation could be found, but the remaining six reactions were very interesting. It was customary to use "giving" sets assembled and sterilized by the transfusion orderlies, or sets recently issued from the Army Blood Supply Depot. One day it was discovered that an orderly had collected sets sterilized eighteen months previously. Although the "cellophane" wrapping had lost its "crispness," these sets were still sealed, and it was therefore decided to use them. Out of five infusions three subjects developed Grade II reactions. The following day only three subjects were reinfused with these old sets, and all developed a febrile reaction, including one Grade III reaction.

No febrile reactions have followed the 56 infusions of glucose-saline, but it is of interest to note one false reaction. In this particular case it was found that the subject had a temperature of 102° F. (38.9° C.) four hours after the infusion. He was, however, found to be suffering from acute follicular tonsillitis.

Infusions

Duration of Blood Storage.—In most cases the reinfusion was started within one hour of collection, but in 11 cases the blood was stored for two days and in 20 cases for seven days before reinfusion. The blood was cleanly and properly collected, and immediately, accurately, and continuously refrigerated between 2 and 6° C. In none of these 31 cases did a febrile reaction follow the infusion.

Temperature of the Infusion Fluid.—In 36 infusions of glucose-saline the fluid was given at room temperature, while in the other 20 the fluid was warmed in a bucket of water at approximately 40° C. As previously noted, febrile reactions did not occur in any of these saline infusions. The infusions of blood were performed at room temperature, the refrigerated blood being warmed to that temperature. In three cases blood was taken straight from the refrigerator and immediately reinfused (as was the practice in several field transfusion units on active service) without any reaction apart from venous spasm in one case, described below.

Rate of Administration.—The saline infusions were given at a standard rate of approximately 40 ml. a minute and no reactions were observed. With blood the usual rate of administration was 20 ml. a minute, but in 24 cases a rapid infusion was given at rates varying from 80 to 110 ml. a

minute. The following observations were made during these 24 rapid infusions:

Nature of Reaction	No. of Cases in which Observed
Rise in temperature	0
Flushing	2
Venous filling	9
Fullness in head	7
Shivering and feeling of cold	7
Feeling cold without shivering	3
Tingling of lips	14

These reactions were transient, and in each case passed off a few minutes after ending the infusion.

Venous Spasm

This was observed in five cases only. In three of these the intense local spasm of the vein was enough to interfere with the administration, but on the application of local heat the spasm was relieved and the infusion given without difficulty. In all five cases it seemed to be the mechanical insertion of the needle which caused the spasm. Veins which were large, obviously visible, and easily palpable suddenly became small and almost impalpable on the insertion of the needle. In one case, however, the temperature of the fluid was an additional factor causing venous spasm, and this case is described in detail.

The subject was a healthy young man with very large veins. When he had been venesected it had been noted that his large vein suddenly became small on the insertion of the needle, but the spasm rapidly passed off. On this particular occasion the blood for reinfusion, which had been stored for two days, was administered at the temperature of the refrigerator. The venepuncture of an anteubital vein was cleanly performed, but the vein immediately went into spasm. In spite of the fluid's being cold the spasm appeared to pass off and 540 ml. was given without difficulty in half an hour. The only subjective phenomenon was that he felt his arm cold, and it was observed that the skin of the upper arm was much colder on the infusion arm, although the skin of the forearm appeared equally warm on the two sides. No difference in colour was noted between the two sides. About half an hour after the end of the infusion the subject complained of "stiffness" of the upper arm used for the infusion. There was at this time full movement at the elbow, but the skin of the upper arm was intensely cold. The subject was reassured, but two hours later he reported acute stiffness of his elbow.

On examination only a few degrees of flexion at the elbow was possible and supination was limited. There was acute tenderness over the biceps, particularly over the tendon, and this was limited to the muscle. The skin was now equally warm on both arms and the brachial pulses were equal. There was no evidence of any discoloration; the vein which had been used for the infusion was still patent and there was no tenderness over it. Otherwise the subject felt perfectly well and his pulse and temperature were normal. The diameter of the upper arm was 2 in. (5 cm.) greater on the affected side than on the other. He was given a hot bath and a sedative and sent to bed. The next day his movements at the elbow were almost normal and he had only slight stiffness. The difference in diameter persisted, but there was only slight tenderness over the biceps. No abnormality of the vein was detected. Then 48 hours after the infusion he noticed a bluish discoloration over the medial aspect of his forearm. Movement at the elbow was now normal, the difference in diameter was 1½ in. (3.75 cm.), and there was no discoloration in relation to the vein used for the infusion. The vein itself was patent and there was no pain or tenderness along it. The discoloration spread along the medial aspect of the forearm, but the whole condition cleared up in a few days, the normal difference in diameter between the two arms being 1 in. (2.5 cm.).

A similar phenomenon was observed in another of the five cases of venous spasm, although in this case the reinfused blood was at room temperature. Here also it had been noted that the vein went into spasm during the collection of the blood. The venepuncture for the infusion was cleanly performed, and 100 ml. was infused without

difficulty in three minutes in spite of the fact that the vein had gone into spasm at the insertion of the needle. Then the subject complained of intense pain over the upper arm and the infusion was stopped. The subsequent course was very similar to the previous case, with restricted movement at the elbow and swelling of and intense tenderness over the biceps muscle. The discoloration did not appear until 72 hours after the infusion.

It is suggested that these two cases were not examples of extravasation of blood from faulty venepuncture, because of the apparently clean insertion of the needle, the ease of administration, the absence of pain around the site of puncture, and the long delay in the appearance of the discoloration. Rather it is suggested that there was an intense spasm of veins draining the biceps muscle, with rupture of some tributaries within the muscle. To support this we have the swelling and tenderness confined to the biceps and the delayed appearance of discoloration as the blood slowly tracked down.

Other Reactions

Thrombosis of the vein used for reinfusion occurred in only three cases. Apart from slight pain there were no other subjective features in these cases of thrombosis. There were no cases of *infection* following the venepuncture or the use of the local analgesic. Mild *sensitivity* to the "elastoplast" dressings used was seen in only one case. Air embolism never occurred, but the danger was constantly emphasized, particularly from the emptying of the transfusion bottle when using the Army overseas pattern set with its one-way air inlet.

Careful records were kept of reactions occurring during or after venesection. There were no cases of fainting either during or after the collection of blood. Out of the 324 blood collections there were only six cases which showed mild incipient and transient features of the vasovagal syndrome. These all occurred a few minutes after the blood collection had ended. There were no cases of delayed faints among the 31 subjects in whom the blood was not immediately reinfused.

Discussion

Kordenat and Smithies (1925) and Riddell (1939) state that nearly all transfusions of fresh blood were associated with a rise of temperature even though this might be symptomless. Again, Jewesbury (1941) states that a rigor occurs in about 8% of fresh blood transfusions. These febrile reactions are caused by foreign protein, dead bacteria, stale distilled water, impure chemicals, and, above all, dirty apparatus. It was shown by Lewisohn and Rosenthal (1933) that the incidence of febrile reactions was reduced from 12% to 1.2% by the scrupulous cleaning of apparatus and by using freshly distilled water. The present observations show that with fresh blood, stored blood, and crystalloid solutions febrile reactions can be reduced to almost negligible proportions provided every care is taken in the preparation of the solutions and apparatus and in the collection and storage of the blood. Whitby (1942) emphasizes the care that is necessary in the handling of stored blood in order to avoid these hazards.

Maycock and Whitby (1941) state that too fast a rate can cause a rigor, which ceases instantly if the rate is slowed. In the present observations no rigors occurred in the cases of rapid infusions, but some of the subjects receiving them felt cold and shivery. This shivering passed off almost immediately after the end of the infusion, and it should be noted that no rise of temperature was associated with the shivering. In our opinion these shivering attacks and rigors associated with rapid infusions are not true

febrile reactions. In our clinical experience of true febrile transfusion reactions it has been noted that slowing the rate of administration does not abolish the shivering of a true febrile reaction. The exact nature of these non-febrile shivering 'attacks' or rigors sometimes associated with a rapid transfusion is not clear. It is of interest to note in the present series that the three cases of shivering and the three cases of feeling cold during the rapid infusion did not show any signs of vasodilatation such as fullness in the head, flushing, or distended peripheral veins; indeed, in three of these six cases the subject became pale. Conversely, none of the subjects showing signs of vasodilatation during the rapid infusions developed a feeling of cold or shivering. It is suggested that the sudden introduction of a large volume of fluid at room temperature into the circulation produces in some subjects a compensatory vasoconstriction, with a resultant feeling of cold. In a previous observation made by one of us (Sharpey-Schafer and Wallace, 1942a, 1942b) on rapid infusions in subjects who had been venesected and then infused with serum there were no rigors or shivering attacks even in those who showed no signs of vasodilatation, although the volumes of fluid infused were much larger than in the present series. In the previous series, however, the infused fluid was warmed to body temperature, whereas in the present one it was given at room temperature.

If this explanation of these shiverings and rigors associated with rapid transfusions is the correct one it raises the practical problem of the advisability of warming transfusion fluids. It is theoretically sound to warm all transfusion fluids to body temperature, but in practice in a busy resuscitation ward this has usually proved impossible. In those cases of oligæmic shock which have developed a shivering attack or a rigor during a rapid infusion of fluid at room temperature it has been our practice to continue the rapid infusion if the level of the blood pressure demanded a rapid transfusion. Our impression has been that those suffering from oligæmic shock who had developed these shivering attacks improved dramatically with the onset of the shivering just as if there had been a stimulation of the vasomotor centre. It must be emphasized, however, that this rapid infusion of blood should be continued only if it is not a haemolytic reaction or circulatory overloading which is causing the rigor.

It was shown by Sharpey-Schafer and Wallace (1942b) that when the blood volume was reduced by a large venesection (1,000 ml.) injection of serum or saline in similar quantities at a rapid rate produced little or no change in venous pressure or other signs or symptoms of vasodilatation. In the present series, however, where the venesection was smaller and the replacement fluid was blood, some subjects did show a transient rise in venous pressure and manifestations of vasodilatation. After a large venesection in man haemodilution is slow, but in some cases there is an immediate small dilution (Stead, 1940; Wallace and Sharpey-Schafer, 1941). In a small venesection (440 ml.) this immediate dilution may be enough to restore the blood volume to its original level, and it is probable that the cases showing vasodilatation in the present series were those which had already restored their blood volumes by this rapid initial dilution.

The complete absence of faints following blood collection and the low incidence of even mild vasovagal attacks are probably explained by the type of donor with whom we were dealing. These orderlies were intensely interested in transfusion work, and most of them had volunteered for it. The whole atmosphere was friendly and reassuring, for although most of the venepunctures were performed by orderlies there was always a medical officer in attendance.

Summary

The collection of 440 ml. of blood and the reinfusion of this citrated blood were performed on 324 individuals. An infusion of 540 ml. of glucose-saline was given to 56 individuals.

Febrile reactions occurred in nine of the 324 infusions of blood, but in none of the infusions of glucose-saline. The causes of these reactions are elucidated.

Febrile reactions are no more common with stored blood than with fresh blood, provided the blood is cleanly collected and properly stored.

The effect of the temperature and the rate of administration of the infused fluid on reactions are described.

Venous spasm, thrombosis, and mild vasovagal features were observed in a few cases.

The avoidance of pyrexial reactions and the cause of rigors associated with rapid infusions are discussed.

These observations were made during the routine training of transfusion orderlies, and we thank our commanding officer, Brigadier Sir Lionel Whitby, for his great interest and help in the training of personnel in transfusion and resuscitation.

ISO-IMMUNIZATION BY THE BLOOD FACTOR N

BY

L. DE KROMME

AND

L. A. M. VAN DER SPEK, M.D.

(From the Blood Transfusion Laboratory of the Onze Lieve Vrouwe Gasthuis, Amsterdam)

It is well known that blood factors of the ABO, MN, and Rh systems are found in the erythrocytes of every human being. In contrast with the ABO system, no naturally occurring antibodies directed against the Rh factors are found in the plasma. Immune or normal M and N antibodies are very rarely observed in human sera in spite of the fact that in giving blood transfusions no account is taken of the M and N blood types of donor and recipient. From this we may conclude that the M and N factors are very weak antigens for human beings.

Allot and Holman (1947) found several irregular antibodies, including one anti-N agglutinin. The late G. L. Taylor also found normal N antibodies in one case (Callender and Race, 1946).

So far as we know, only two cases of an N immunization are described in the literature. The first was published in 1943 by Singer. It concerned a Rh-positive patient with blood type M. This patient had received a transfusion with Rh-positive N blood. After further transfusions, again with Rh-positive N blood, the patient showed a haemolytic reaction. Anti-N agglutinins were indicated in the serum. Transfusion with M blood was endured without any reaction. The second case was described in 1946 by Callender and Race. A patient suffering from lupus

erythematosus diffusus displayed a great aptitude in forming various rare antibodies—so much so that some "new" blood factors were discovered by the authors. During the course of her illness, in which a number of large and small transfusions were given, anti-c (anti-Hr) and anti-N antibodies were found in the plasma. These two cases of iso-sensitization by the N antigen occurred in patients who were immunized in consequence of blood transfusions.

In recent years we have become conversant with another method of iso-sensitization—namely, with the immunization of mothers by Rh and A or B antigens of the foetus. It is now generally known that iso-antibodies formed during pregnancy are responsible for erythroblastosis foetalis. The question arises whether an antagonism in MN blood types of mother and child might be responsible for symptoms of the newborn. No cases of iso-sensitization by the N antigen in MN heterospecific pregnancies are mentioned in the literature so far. At the end of 1946 we came into contact with the following case.

Case History

A married woman, aged 33, had had her first pregnancy end in 1944 at term with the birth of a foetus maceratus. Her second, in 1945, ended at term after a long partus. A living child was born, which died, however, some hours later. From this infant no further clinical data could be obtained. In the seventh month of her third pregnancy a specimen of her blood was sent to us by Dr. Castelein, St. Elisabeth Hospital, Tilburg. It was Rh-positive and had the blood formula R,R, (CDe/cDe)-A-M. In the combination CDe/cDe of rhesus elementary antigens only d is missing. Concerning the possibility of a sensitization within the Rh system, therefore, this mother theoretically should be able to form only anti-d antibodies, but this antibody could not be found in the serum at any time.

In the meantime we also received blood from the husband for examination. He also was Rh-positive and had the blood formula R,r (CDe/cde)-O-MN. Contrary to our expectation the blood cells of the man were agglutinated by the serum of the woman. By testing a large number of A and O bloods with the serum of the mother we obtained some more positive reactions, without finding any connexion with the factor d.

With regard to the MN types, it was possible that the woman (M) had been immunized by the factor N inherited from the husband (MN)—a possibility overlooked before. Indeed, the serum of the mother was found to contain anti-N antibodies and to agglutinate only N or MN blood (Group A or O being used). We supposed the N antibodies originated from the iso-immunization during the preceding pregnancy(ies), and that both affected foetuses had inherited the N antigen from the father. Naturally this could not now be proved. If the N antibodies had made both children ill it would be expected that the subsequent child, if MN, would show symptoms. If the child turned out to be NM then it might be expected not to show symptoms.

Three months after our examination caesarean section was carried out. Blood from the umbilical cord was sent to us for examination. The child was Rh-positive and had the formula R,r (cDe/cde)-O-M. It is certain that this child could not have suffered from the existing abnormal anti-N antibodies, which, moreover, could not be detected in his own serum. As we expected, the baby seemed to be completely normal at birth and it developed like a healthy child. We believe that the occurrence of the anti-N agglutinins in the mother's plasma must be due to sensitization by foetal agglutinogens during the first two pregnancies. Indeed, though it is remarkable that the first child was affected, we are fairly certain of the correctness of this assumption, since 10 months after the second pregnancy the agglutinin titre seemed to be rather low (<4), tending to decrease slowly but continuously during the following three months—the last three months of the third pregnancy. Also, anti-N agglutinins could not be detected in the child's plasma at the moment of birth.

Comment

The question arises whether we are entitled to impute the death of the first two children to the action of the N antibodies detected in the mother's plasma. Of course we cannot be sure. Against this suggestion is the fact that the agglutinin was active only at room or colder temperatures, but inactive at 37° C. On the other hand the possibility cannot be absolutely excluded that under such circumstances as those present *in vivo* these cold agglutinins are able to damage the erythrocytes at body temperature. In connexion with this we recall the observations of Weiner, who, by using his conglutination technique in a case of acquired haemolytic anaemia, succeeded in demonstrating auto-agglutination *in vitro* at body temperature as well as in the refrigerator. It is clear that the circumstances *in vivo* show a greater resemblance to those of the conglutination reaction than to those of the agglutination reaction. Moreover, we do not know how high the anti-N titre had been during the first two pregnancies, and we do not know if the anti-N agglutinins then present *in vitro* were active only at lower temperatures.

Summary

In the serum of a pregnant woman anti-N agglutinins have been detected. These agglutinins are considered to be immune iso-antibodies.

The possibility of these anti-N antibodies being responsible for a stillbirth as well as for the death of a child some hours after birth is discussed.

We wish to thank Dr. R. R. Race for his kindness in confirming our serological findings and for his interest in our work.

Medical Memoranda

Rupture of the Stomach in an African Child

Rupture of the stomach in the following case was, we believe, caused by gross gastric distension due to the action of gas-forming fermentative organisms, and we consider this unusual case may be of some interest.

CASE REPORT

A 5-year-old Acholi boy was brought to Mulago Hospital at 4 p.m. on April 26, 1946, for the fifth injection (N.A.B. and bismuth) in a course of treatment for yaws. The child was examined by an assistant medical officer, who, finding a solid mobile tumour in the hypogastrium, admitted him to hospital for investigation. Food was brought by the mother and given to the child at 6 p.m. At 11 p.m. the patient complained of abdominal pain, and there was vomiting of mucus. The condition progressed during the night, and when he was seen by one of us (R. G. L.) at 8 o'clock the next morning there was considerable distension confined to the epigastric and right hypochondriac regions.

The general condition was very poor, the patient being only semi-conscious. Continuous intravenous saline was given, and laparotomy was performed at 11 a.m. The abdominal distension by that time had increased and had become generalized.

At operation the mobile abdominal tumour was found to be a spleen with a very long mesentery; there was nothing to suggest that recent displacement had occurred. The peritoneal cavity was grossly distended with gas and fluid, but there was no evidence of peritonitis. The stomach was spherical in shape and about 7 in. (17.5 cm.) in diameter. There was a tear about 3 in. (7.5 cm.) long in the posterior wall of the stomach beginning at the cardiac sphincter. From this tear large amounts of fluid and gas poured out as soon as the stomach was handled. The peritoneal and gastric contents had a very penetrating smell which, though clearly alcoholic, did not

resemble any form of native beer. Closure of the tear was attempted, but the child died.

Necropsy was performed three hours after death (J. N. P. D.). In view of the history a careful search was made for evidence of trauma, but nothing was found. Relevant findings were confined to the abdomen. An enlarged spleen was lying in the right iliac fossa, its long mesentery lying across the transverse colon but below the stomach and causing congestion in the part of the pancreas which was lying underneath. The peritoneal cavity was full of gas and of a frothy grey-white fluid, like thin gruel, in which were floating solid particles of food. A curious penetrating alcoholic odour was given off. This could not be identified by anyone present, including the head African mortuary attendant—a great expert in recognizing post-mortem alcoholic odours.

The posterior wall of the stomach showed a linear tear 3 in. long that extended about 1/2 in. (1.25 cm.) into the oesophagus. The stomach otherwise was normal. It was filled with gas and liquid similar to that in the peritoneum; the fluid continued to ferment and to produce quantities of gas and ethyl alcohol from the particles of sweet potatoes which were identified in the peritoneal fluid.

Microscopically the stomach wall was normal and showed no evidence of any condition likely to lead to rupture. The peritoneal contents on culture grew a mixture of organisms, including Gram-negative cocci and bacilli. This mixture of organisms fermented a wide range of sugars and produced large quantities of gas, but unfortunately the cultures were lost and further investigation was impossible.

DISCUSSION

Close inquiry revealed that no native medicine or beer had been given to the child, and, as stated, there was no evidence of trauma. We suggest that the fermentation of the evening meal of sweet potato produced gas under such pressure as to rupture the stomach. It may be that a very slight trauma inflicted on a greatly distended stomach might have caused the rupture. Clinically it appeared clear that at 8 a.m. the distension was of gastric origin, whereas by 11 a.m. general distension had occurred following intraperitoneal rupture, and during this time the child was lying in bed. By European standards the meals taken by African children are enormous, which probably accounts for their thinner stomach walls, with presumably a greater tendency to rupture. In this case there seemed to be no reason why the gas should not have been eructated. The dependent spleen seemed to be of no concern here.

It is perhaps of interest to point out that the overdistension of the African stomach not infrequently leads to death because of the inhaling of vomitus. This was the cause of death in six cases out of 100 necropsies performed by police request on cases of sudden death not due to violence recorded at Mulago Hospital.

A further case is on record of a young male African child whose death was due to shock from rupture of a grossly over-distended stomach, the result of an enormous meal. As in the case here recorded there was no history or sign of disease or trauma.

Advances in medical knowledge are reported in an increasingly large number of publications, and it is now more difficult than ever to discover every paper published which has some bearing on a particular topic, such as leprosy. The British Empire Leprosy Relief Association, therefore, has started publishing monographs by recognized authorities covering recent advances in knowledge on various aspects of leprosy. The first monograph is a well-produced illustrated pamphlet entitled *The Lepromin Test*, by Dr. Dharmendra, and is obtainable from B.E.L.R.A., 167, Victoria Street, London, S.W.1 (price 2s. 6d.). Dr. Dharmendra considers the active principle of lepromin to be a protein antigen of the leprosy bacillus. He discusses a method for preparing lepromin standardized by the weight of dry leprosy bacilli. He then considers the results of the test in cases of leprosy, contacts, and non-contacts, and concludes that a positive reaction is an allergic phenomenon. He regards the test as of definite prognostic value in all cases of leprosy, but of little use in diagnosis or treatment.

Reviews

MEDICINE IN TRANSITION

Nursing and Nursing Education. By Agnes Gelinus, R.N. *Health Insurance in the United States.* By Nathan Sinai, Dr.P.H., O. W. Anderson, and Melvin L. Dollar. *Medical Addenda.* Related Essays on Medicine and the Changing Order. *Medicine in the Changing Order.* New York: Commonwealth Fund. London: Geoffrey Cumberlege. (\$1.00 or 6s. \$1.50 or 8s. 6d. \$1.75 or 10s. 6d. \$2.00 or 11s. 6d. respectively.)

The U.S.A. is a big country and it does big things in a big way. In 1942 the New York Academy of Medicine appointed a strong committee representing every side of opinion, medical and allied, to consider the present and future outlook of medicine. It began by defining its objectives as follows: "To be informed on the nature, quality, and direction of the economic and social changes that are taking place now and are clearly forecast for the immediate future; to define in particular how these changes are likely to affect medicine in its various aspects; to determine how the best elements in the science of medicine and in its services to the public may be preserved and embodied in whatever new social order may ultimately develop."

During the years that have elapsed the Committee has issued some ten volumes of monographs on every aspect of its task; the latest are *Nursing and Nursing Education*, *Health Insurance in the U.S.A.*, a volume of *Medical Addenda*, and *Medicine in the Changing Order*. Owing to the exigencies of space it is necessary to confine this review to the last named, in which the Committee states its considered views on the subject of its reference. It is very frank about what it thinks are the defects in the present provision of medical care. It believes that both the public and the profession want a great extension of it in quantity and in quality. It finds public health measures—"the first steps in the evolution of good medical care"—to be very inadequate in many areas. It notes with pleasure the great increase to the number of hospitals, but judges their quality in many areas to be in great need of improvement.

There is a strong disposition in many young doctors to avoid the rural areas not only on financial grounds. The provision of good hospitals accompanied by group practice (which it strongly recommends) would be a great attraction to many young men, and it advocates their being sent in their clinical years to approved rural hospitals by arrangement between the hospitals and the medical schools.

Much attention is given to medical insurance and to the numerous experiments of a voluntary nature made in recent years. The Committee comes down heavily on the side of voluntary schemes, and hopes that more encouragement will be given to people above the lower-paid groups to enter them, since they are a better insurance risk and their presence would help to popularize and to improve the quality and status of such schemes. "Voluntary insurance," it says, "leaves the physician the play of initiative and resourcefulness and individual responsibility." The report advocates Government grants and employers' contributions on behalf of the lower-paid people "as a sound alternative to an overall programme of compulsory insurance." The schemes, it thinks, "are much safer and more adaptable than compulsory plans, the consequences of which are at best uncertain and are in any event irrevocable." "It is on a voluntary basis that the great progress of medicine has been achieved in the past, and it is thus that continuance of progress can be assured." It is rather startling to read, "We do know from European experience that even as the general level of medical practice is lowered its costs are raised."

Discussing the various methods of payment of doctors the Committee says, "Abuses are possible in all methods of payment, whether fee for service, capitation, or salary. Thus no valid statement can be made that this or that system is best *per se*. There lies the great advantage of voluntary plans as compared with compulsory: they permit wide local experimentation in working out the system best adapted to a given time and place." While there is room for differences of opinion on

many of the knotty points raised in this report, there can be no doubt that the Committee has done its work ably and thoroughly and that its volumes cannot be ignored by students of medical sociology wherever they may be.

ALFRED COX.

BLOOD PROTEINS

Die Bluteiweisskörper des Menschen. By F. Wührmann and C. H. Wunderly. (Pp. 354; illustrated. 36 Swiss francs.) Basle: Benno Schwabe. 1947.

This book is mainly about the value of examining the blood proteins in human clinical practice. After reviewing the methods available for this type of investigation the authors present the results of the experience gained over a number of years by themselves and their colleagues on clinical material. The methods used in their investigations were: (1) the salting-out curve in strong phosphate buffers; (2) the electrophoretic pattern; (3) the Weltmann test; (4) the cadmium-sulphate turbidity test, a recently developed simple clinical test; (5) the Takata-Ara reaction; and (6) the sedimentation rate.

The following correlations of empirical tests with the electrophoretic pattern may be noted. The Weltmann band was found to be broad when the γ -globulin was very high, and narrowed by an increased α - or β -globulin. The cadmium turbidity test was given when a high γ - or α -globulin was present and inhibited by an excess of β -globulin. The Takata-Ara reaction was given when a high β - or γ -globulin was present. The authors discuss the blood-protein reactions in various diseases of importance in practice and disturbances of the blood proteins. This part of the book is well illustrated by appropriate data, most notably by the presentation of salting-out curves and electrophoretic patterns.

The six types of reaction pattern distinguished are (1) acute inflammations; (2) subacute and chronic inflammatory processes; (3) diffuse liver-cell injury; (4) the nephrotic symptom complex; (5) γ -plasmacytoma; (6) β -plasmacytoma. Abnormal fibrinogen values were most common in diseases involving abnormalities of blood coagulation and haemorrhagic diatheses. Disturbances of serum globulin were mostly related to malignant tumours such as leukaemia, sarcoma, carcinoma, and particularly to the plasmacytomas. They do not, however, provide a specific test for tumours, since they may occur in inflammatory processes, especially chronic forms which might be diagnosed as malignant tumours; but they do afford an interesting basis for subdividing the plasmacytomas according to whether the γ - or β -globulin is abnormally high. The changes in serum globulins were usefully followed by electrophoretic methods in acute and chronic infections, and in these diseases, especially in phthisis, it was the α -globulin which was mainly affected. Albumin, when it was disturbed, was always lowered, and this was nearly always the cause of hypoproteinaemia.

The observations embodied in this book are both empirical and fundamental, so that they should be of interest to the research worker as well as the clinician.

D. P. CUTHBERTSON.

EXAMINING THE SURGICAL CASE

Clinical Methods in Surgery. By K. Das, M.B., F.R.C.S. (Pp. 240; 199 illustrations. Rs. 20 or 35s.) Calcutta: The City Book Company. 1947.

The student beginning his surgical work in the wards is usually given some elementary lessons in case-taking to help him in his task, but some of the printed guides which accompany the lectures are mere lists of instructions—dull and uninspiring. The author of this book states that he has tried to answer the question, "How shall I investigate this case?" and on the whole he has answered it satisfactorily. In 41 chapters he discusses the method of examining the various conditions which the surgeon meets with, and at the end of each section he briefly, perhaps too briefly, enumerates the common causes of the condition which need differentiation. The book is very well produced and the illustrations are for the most part excellent; in Fig. 70, however, we think one eye should be shown covered

up by one hand so that the consensual reflex may be avoided. The necessity for brevity has in some instances resulted in descriptions which may have an unexpected effect on the reader, as for example when he reads concerning duodenal ulcer, "a young man, quite busy, swallows his meals hastily at irregular intervals between cigarettes and telephone calls."

In the preface the author states that the book was composed in a fateful year during which continual disturbances prevailed in the city of Calcutta, disturbances which considerably hindered his choice of material. It is to his credit that in spite of this drawback he has succeeded in producing a book which should be of considerable assistance to the beginner in surgery.

SPANISH-ENGLISH DICTIONARY

Spanish-English Medical Dictionary. By Maurice McElligott, F.R.C.S.I., D.P.H. (Pp. 250. 12s. 6d.) London: H. K. Lewis and Co., Ltd. 1946.

The author of this small dictionary says in the preface that he has compiled it after many years of search for the Spanish equivalents of English medical terms. It contains 14,000 Spanish words translated into their English equivalents, but there are many lacunae, more especially among the less ordinary terms. He gives no explanations or examples of how to use the words, and the dictionary therefore does not meet the need of translators. The volume might be more correctly described as a glossary and be of use in checking spelling or in conjunction with works of reference. Used alone, its adequacy as a dictionary is questionable. The author is apparently aware of these limitations, for he asks in his preface that readers inform him of any omissions they may observe so that they may be made good in future editions. He has taken every precaution to ensure the accuracy of the words listed, and the orthography of the English terms is that of the *Oxford English Dictionary*. He proposes to follow this dictionary with a companion volume of English-Spanish medical terms.

V. McGUIRE.

IDEALISM IN ACTION

Albert Schweitzer. The Man and his Mind. By George Seaver. (Pp. 346; 30 illustrations. 18s.) London: Adam and Charles Black. 1947.

Even the irreligious and the non-musical know the name of Albert Schweitzer. Born in Alsace in 1875, he had before he was 30 acquired a European reputation in music, philosophy, and theology. An outstanding organist, he early illustrated his capacity for taking pains by becoming not only expert in the craft of organ-building but also the leading interpreter of Bach. At 30 he decided to take a medical qualification so that he might carry healing to the sick African, and the greater part of the second half of his life has been spent in Equatorial Africa working in a mission hospital built by himself. Reverence for life has been his philosophical keyword and compassion the mainspring of his action. His biographer regards him as "probably the most gifted genius of our age, as well as its most prophetic thinker."

These are large claims, and some of the interest of the biography lies in the assessment of them. One concludes that while his gifts are incomparable the quality of his thought is less striking, and his philosophic concept of reverence for life has hardly the basic comprehensiveness which he attributes to it. The truly remarkable thing about Schweitzer is his personality and the ethic that inspires it. Rarely does the artist and thinker voluntarily renounce his art and his thought for a life of action in physical discomfort and danger. If the twentieth century is hurrying to its materialist doom it cannot complain that it has lacked extraordinary and topical examples of the strength of idealism in action. The lives of Gandhi and Nansen, as well as of Schweitzer, come readily to mind. Those who read biography to enjoy the spectacle of littleness in great men (and I confess to being encouraged by even the tiniest wart on the illustrious nose) should avoid this life of Schweitzer as they would that of the Archangel Gabriel.

D. V. HURBLE.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

Dermatoses Among Gas and Tar Workers. By W. D. Jenkins, J.P., B.A., M.R.C.S., L.R.C.P. (Pp. 54. 25s.) Bristol: John Wright. 1948.

A monograph, with illustrations.

Fundamentals of Neurology. By E. Gardner, M.D. (Pp. 336. 24s.) Philadelphia and London: W. B. Saunders. 1947.

An introduction for medical students.

Textbook of Bacteriology. By T. B. Rice, A.M., M.D. 4th ed. (Pp. 603. 32s. 6d.) Philadelphia and London: W. B. Saunders. 1947.

A short textbook for medical students and practitioners.

Textbook of Surgery for Nurses. By E. S. Stafford, B.A., M.D., F.A.C.S., and D. Diller, B.A., R.N. (Pp. 577. 16s. 6d.) Philadelphia and London: W. B. Saunders. 1947.

Intended to provide general surgical information for the student nurse.

Cineplasty. By H. H. Kessler, M.D., Ph.D. (Pp. 201. 35s.) Oxford: Blackwell Scientific Publications. 1947.

An account of operative techniques, prostheses, and rehabilitation.

Osteotomy of the Long Bones. By H. Milch, M.D. (Pp. 294. 35s.) Oxford: Blackwell Scientific Publications. 1947.

A practical account of osteotomy, with many illustrations.

Sexual Behaviour in the Human Male. By A. C. Kinsey et al. (Pp. 804. 32s. 6d.) London: W. B. Saunders. 1948.

A compendious account of the sexual conduct of men in the U.S.A.

P-Q-R-S-T. A Guide to Electrocardiogram Interpretation. By J. E. F. Riseman, M.D., 2nd ed. (Pp. 84. 17s. 6d.) New York: The Macmillan Company. 1947.

Many diagrams of E.C.G. records and notes on interpreting their significance.

The Child's Hearing for Speech. By M. D. Sheridan, M.A., M.D., D.C.H., L.R.A.M. (Pp. 120. 10s. 6d.) London: Methuen. 1948.

An investigation into the relation between speech, hearing, and intelligence in childhood.

Principles of Medical Statistics. By A. Bradford Hill, D.Sc., Ph.D. 4th ed. (Pp. 252. 10s. 6d.) London: The Lancet. 1948.

A practical introduction to statistics for the medical man.

The Science and Practice of Surgery. By W. H. C. Romanis, M.A., M.B., M.Ch., F.R.C.S., F.R.S.Ed., and P. H. Mitchiner, C.B., C.B.E., F.D., M.D., M.S., F.R.C.S., D.Ch. Vols. I and II. 8th ed. (Pp. 892, vol. I; 955, vol. II. 25s. each vol.) London: J. and A. Churchill. 1948.

This well-known textbook includes new material on plastic surgery, x-ray therapy and diagnosis, anaesthesia, and venereal diseases.

Diseases of the Breast. By Sir Crisp English, K.C.M.G., F.R.C.S. (Pp. 128. 8s. 6d.) London: J. and A. Churchill. 1948.

A short account based on the author's experience.

Surgery of the Ambulatory Patient. By L. K. Ferguson, A.B., M.D., F.A.C.S. 2nd ed. (Pp. 932. 72s.) London: J. B. Lippincott. 1947.

A practical manual of minor surgery intended for house-surgeons and general practitioners.

Textbook of Endocrinology. By Hans Selye, M.D., Ph.D., D.Sc., F.R.S.Can. (Pp. 914. \$10.24.) Montreal: Acta Endocrinologica. 1947.

A textbook for student and physician.

Milk Products. By W. C. Harvey, M.D., D.P.H., F.R.San.I., and H. Hill, F.R.San.I., A.M.I.S.E., F.S.I.A. 2nd ed. (Pp. 341. 30s.) London: H. K. Lewis. 1948.

A practical manual on the manufacture, composition, and examination of edible milk products.

Textbook of the Nervous System. By H. C. Elliott, M.A., Ph.D. (Pp. 384. 48s.) London: J. B. Lippincott. 1947.

An account of the anatomy of the nervous system, with many diagrams, for medical students.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY APRIL 3 1948

THE PATIENT'S RECORDS

Any efficient system of recording admissions to a hospital should clearly permit, with a minimum of trouble, the certain identification of the individual patient's documents, with all particulars of his (or her) previous entries to the same, or indeed to another, institution. Such information may be needed either for administrative reasons or to reveal the past history of the patient's illnesses and the treatment given, while at the same time it will ultimately serve the ends of research. In a brief but comprehensive conclusion to their article published on p. 632 Prof. Lancelot Hogben and his colleagues suggest that such a system should ensure: "(a) That a record officer in Beachy Head would assign to a commercial traveller treated for fracture in the Birmingham Accident Hospital and subsequently re-examined in Bedford the same serial number, which would identify his position in the record file of the Birmingham or Bedford institution; and he or she would hence be able to obtain therefrom information relevant to treatment with minimum effort and delay. (b) That all records of one and the same individual successively admitted to one and the same institution either as an in-patient or as an out-patient would be available for research in one and the same niche in its file of medical documents without recourse to a name-address admission-and-discharge register." They point out that the use of birth names may lead in any large-scale institution, and *a fortiori* in any regional organization, to insuperable difficulties—in the Birmingham United Hospital alone, for instance, there would be in 10 years some thousands of patients named Smith or Jones. This dilemma has led them to develop an ingenious system of numbering the patient from information given by him, in such a way, it is hoped, that the same number would always be allocated to the same individual whenever or wherever admitted to hospital.

Their method is based upon a punch-card system, but in small institutions could easily be used without it. The three main items of information required are merely the Christian names, surname, and date of birth of the patient, all of which would normally be required by a records department and are not likely to give rise to any suspicion of regimentation. The patient's number is then very simply determined from code lists provided on the basis of (a) the first Christian name (the whole name if a common one, the initial letter if less common); (b) the first two or three letters of the surname, except for Smith, which needs a number to itself; and (c) the exact date of birth. Thus the identity of Mr. Aneurin Bevan, born on November 15, 1897, can be succinctly, comprehensively, and probably uniquely comprised under the number 0509151197.

In the development of this scheme Hogben and his colleagues have worked hard to ensure an adequate allocation of code numbers to prevailing Christian and surnames. They point out that their data, taken from the Birmingham area, are not necessarily representative of the country as a whole, but as regards surnames a comparison of some interest can be made. Using their code list C, based upon a Midland telephone directory, it is possible to compute with reasonable accuracy the percentage of names that begin with an A, B, C, etc., and then to see how this distribution compares with that given by Farr for England and Wales in 1853.¹ The results are as follows:

Initial Letter of Surname	Percent		Initial Letter of Surname	Percent	
	Farr	Hogben		Farr	Hogben
A	3	4	M	7	6
B	11	12	N	2	2
C	8	7	P	6	6
D	5	4	R	5	4
E	2	2	S	9	8
F	3	4	T	4	4
G	5	5	W	9	9
H	9	11	I, J, O, Q	5	4
K	2	2	U, V, X, Y, Z	1	1
L	4	4			
			Total	100	99

The agreement, considering the differences in the data both in space and time, is remarkably close. There is likely to be a much greater variation with Christian names, for, of course, parents are greatly influenced by fashion. (See, for instance, *83rd Annual Report of Registrar-General for Scotland, 1937*.) There is a point here of some importance in Hogben's scheme. Some Christian names are so common that to ensure almost certain identification of a patient it is necessary to incorporate birth rank into the code. Thus George, first-born, is number 18, while George, not first-born, is 19. But if this personal information, "easily accessible to the record officer," is to be "liable to no dubiety with respect to its interpretation," a precise definition of birth rank will be essential. For example, should the inquiry relate solely to live-born children, living or dead at the time of the patient's admission? Without careful definition record officers may easily differ in their approach, in the information they elicit, and thus in their allocation of numbers to the same patient.

A less important point is that the maiden name of a married woman must be obtained and used in the coding in order that she may have the same number throughout life. The question may sound odd to the widow of 80 with two husbands on the credit side and a fractured femur on the debit; but hers, perhaps, not to reason why. A much more serious matter, to which the authors do not refer, is the date of birth. Their system is based upon "such characteristics of the individual as do not change in his or her lifetime." The date of birth fulfils the criterion, but does the patient's memory of it? It is clear from past censuses that ages are by no means always given accurately. The amount of error, with increasing education and increasing precision in the question asked, has become less with time, but at the last census in 1931 there still were obvious mis-statements. Between the ages of twenty and seventy there is a marked rise in the numbers of individuals with

¹ 16th Annual Report of the Registrar-General for England and Wales, 1853.

ages ending in the figure 0, and, curiously, also those ending in an 8 (there appears to be a dislike of 7). Some such errors are due merely to haziness about the date of birth, others (principally, it seems, in women) to deliberate mis-statements at certain "critical" ages. It may well be that a record officer will elicit better information than a census enumerator, but it is a moot point whether throughout life there will be "no dubiety" in this respect. Even in school records the entries are not infrequently found to be wrong. This is clearly a matter for inquiry—no doubt a difficult one—for it is fundamental to the coding scheme.

D.D.T. IN USE

The remarkable advantages of D.D.T. have firmly established its value as an insecticide, but it has faults which seriously limit its value if it is not used correctly. It may be useful, therefore, to list these drawbacks and discuss the ways in which they can be overcome.

D.D.T. is primarily a contact insecticide with no action at a distance. Its lethal action is slow, and though it is apparently lethal to all insects and acarines there are a few on which its action is relatively ineffective. The time needed for an insect to acquire a lethal dose from a treated surface is often longer than is commonly supposed. Also, contrary to earlier belief, insects may recover after showing slight signs of D.D.T. poisoning.¹ Reports of susceptible insects such as mosquitoes² and tsetse flies³ picking up a lethal dose in 10–30 seconds relate to artificial conditions of forced contact, perhaps with abnormally favourable surfaces like impermeable glass. Where treatments are applied to the permeable plaster or brickwork surfaces usual in houses the periods of exposure needed for the acquisition of a lethal dose, as distinct from the killing times, are more of the order of an hour for mosquitoes,⁴ twenty-four hours for bed-bugs,⁶ and up to six days for the beetle pests of stored food.⁷ An interesting observation is that the percentage kill of insects does not increase regularly with exposure, as would be expected.⁸ Sometimes great increases in the period of exposure do not result in an increased kill.

Surfaces treated with D.D.T. are irritant to mosquitoes and reduce their resting time.¹ This is a serious matter in malaria control, for it has been shown that partly affected *Anopheles gambiae* may be captured escaping from treated rooms without having remained long enough to pick up a lethal dose.¹⁰ The irritant effect probably applies to other flying insects, and where the total treated surface in a room is small they may escape death by resting for longer periods on untreated areas. This suggests that the value of the little impregnated cards which are now being sold to

destroy house-flies may not be great. In spite of the physical and chemical inertness of D.D.T., residual deposits do gradually lose their effectiveness in the course of time. The rates of loss depend on the underlying surfaces, which may vary from smooth walls to the hair of animals or even collections of water. The cause of the gradual loss may be obvious or obscure, but since a prolongation of insecticidal effect is usually to be desired it is important properly to understand the factors responsible. Another difficulty is that D.D.T. is toxic to beneficial insects and to vertebrates.

The problem of danger to beneficial insects such as bees and certain parasitic and predatory forms is common to all insecticides. D.D.T., because it is more efficient than earlier insecticides, poses the question more emphatically. The toxicity of D.D.T. to vertebrates is not nearly so high as that of many insecticides which have been used for years. Furthermore, its high insecticidal value means that in practice only small concentrations need be used. A comprehensive review of the hazards was published recently.¹¹ A final point is that very little is yet understood about the mechanism of the action of D.D.T. This does not limit its application on empirical lines, but it must be admitted as a deficiency.

The slow lethal action of D.D.T., and the fact that contact with the insect is necessary, depend on essential qualities of D.D.T. which cannot be altered. Its lack of toxic vapour demands contact, and there seems to be no way of accelerating its lethal action to give the rapid "knock-down" produced by pyrethrum, or of increasing its powers against the relatively resistant pests. Where such matters are important it may be necessary to choose another insecticide. The lag in acquiring a lethal dose, the irritant effect, and the non-persistence of D.D.T. present a difficult problem which does not arise in the case of certain pests which are best attacked directly with immediate heavy contamination. The 10% D.D.T. dust kills human lice¹² or the fleas of domestic animals¹³ or rats¹⁴ in a short time, and the relatively short residual action (ten days or so) is still long enough to end the infestation. Other pests cannot benefit from the slow acquisition of the lethal dose or from possible irritant action, because they cannot escape from the treated surface. Thus lice are confined to impregnated underwear¹⁵ and bed-bugs cannot escape from treated walls and furniture.⁶ Pests which may benefit are flying insects such as house-flies, mosquitoes, tsetse flies, sandflies, etc., which only spend short periods in contact with the treated surfaces. These three problems are interconnected—all concern the relative availability of the insecticide. The D.D.T. must be left in a condition to contaminate the insect rapidly before the irritant effect becomes important, and yet must be sufficiently firmly attached to the surface to

remain effective for a long time. These are difficult conditions to satisfy, and it is clear that many methods of applying D.D.T. are inefficient. With porous materials D.D.T. is absorbed away from the surface and becomes unavailable; it is therefore difficult to render such surfaces insecticidal.^{17 18 19} A possible remedy is to apply the D.D.T. in the form of an emulsion rather than a kerosene solution,¹⁸ or, better still, as an aqueous suspension which leaves the insecticide deposited superficially.¹⁹ Some useful emulsion concentrates have been described.^{20 21} Loss of toxicity from walls may be due perhaps to cleansing operations²²; loss from the hides of treated cattle appears to be due mainly to them licking themselves.²³ In both cases the residual action can be prolonged to some extent by adhesive agents used with the insecticide.^{2 24}

There is disagreement on the exact type of deposit required for maximum insecticidal action. Some workers have found small crystals most active,^{2 6} others say that size is unimportant,²⁶ yet others report that the larger crystals are most toxic.²⁵ Again, it has been noted that D.D.T. crystals are more toxic than supersaturated solutions²⁸; but in another investigation dry crystals were made more toxic by spraying with plain oil.⁶

Interesting results have also been obtained with numerous analogous compounds tested on various insects²⁷ and on white mice,²⁸ and these results may have some bearing on the problem of the mode of action of D.D.T. Progress has also been made in determining the physiological effects of D.D.T. on insect metabolism.^{29 30} Finally, the most important problem in the field of vertebrate poisoning with D.D.T. is the effect of long-continued small doses. One report is already available³¹ and further work is known to be in progress.

TRANSFUSION PRECAUTIONS

Since the end of the war the E.M.S. Transfusion Service in England and Wales has been continued as the National Blood Transfusion Service, and a measure of its need is the increase shown in all its activities during 1946 and 1947. To take two examples—the demands for stored blood in 1947 were greater than in 1946 by some 50,000 bottles, and the issues of dried plasma also showed a considerable increase, rising by some 10,000 bottles. In Scotland the Scottish National Blood Transfusion Association has carried on the service it set up during the war, and in Northern Ireland a transfusion service on the lines of the National Blood Transfusion Service is being established. More blood and plasma are being used now than during the war. Generally, the wider use of transfusion is commendable, for previously many patients who would have benefited were not transfused. On the other hand, blood and plasma are potentially dangerous fluids unless prepared, stored, chosen, and used with extreme care.

The relative profusion of these fluids may be dangerous if the simple but important points to be observed in their use are neglected, if the need for the often complex investigations demanded by modern knowledge of the blood groups is not realized, and if the possible harmful, and sometimes tragic, results of transfusion are not considered. Dr. J. Wallace and Mr. R. D. Richards bring out a number of these points in their article in this issue. They confirm previous observations that properly collected

and refrigerated stored blood is no more productive of reactions than fresh blood. Six of the nine reactions they report are attributed to the use of long-stored sterile giving sets, an event which may occur in any blood bank unless there is close supervision and a steady turn-over. Without constant supervision stored blood itself may be overlooked in the refrigerator and used after the normal expiry period of 3-4 weeks. In fact, blood stored for much longer than this has been transfused.

The wider understanding of the implications of the Rh factor has increased the need for care in the use of blood. Intramuscular and subcutaneous injection, as well as the transfusion of Rh-positive blood to Rh-negative recipients, can cause immunization which is permanent and may have serious results. It is essential that only Rh-compatible blood be given when transfusing any female of child-bearing age or younger, and all women who have been pregnant. Ideally, in males and nulliparous females past the menopause Rh-compatible blood should also be used: at any event an Rh-compatibility test should be made if such people have previously been transfused. The simple expedient of always giving only Rh-negative blood cannot, however, be accepted as a solution of the problem, because it would be wasteful of supplies which are naturally limited and should be reserved for Rh-negative cases. Only in emergencies should the Rh grouping be omitted and Rh-negative blood used irrespective of the Rh group.

It seems established that the transfusion of plasma or serum may be followed in up to 10% of cases by the development of hepatitis, which is sometimes fatal and is indistinguishable from infective hepatitis save for its long incubation period of some 40-120 days. Two such cases have recently been reported in this *Journal*.^{1 2} This risk must always be considered when the use of plasma is contemplated, and plasma should be given only when the benefits likely to accrue from the transfusion outweigh it. Until the various methods now being investigated of destroying the infective agent have been shown to be effective, or a laboratory test to detect infected plasma has been developed, the only methods of control are the withdrawal of batches of plasma shown by transmission of the disease to be infected, the preparation of plasma from small pools, and the rejection of donors with a recent history of jaundice. All plasma now being dried in England is made from pools containing not more than the plasma from 10 bottles of blood, but there is much plasma made from larger pools still in use. The prompt withdrawal of infected material will depend upon the possible association in the clinician's mind of hepatitis with transfusion of plasma, upon the reporting of such cases to the Regional Transfusion Centre, and upon the accurate recording of bottle numbers in the case notes of all patients given plasma. Too often when cases of homologous serum jaundice are reported it is found that no such record has been made.

Constant and close supervision of the use of blood and plasma is required, and in large hospitals at least there would seem to be the need for the appointment of a transfusion officer to supervise not only the administration of the blood bank provided by the Transfusion Service but also to perform the necessary and often complex tests to ensure compatibility and to make any subsequent investigations. The Regional Transfusion Centres can perform much of this work, particularly for the hospitals in their vicinity or for hospitals having no laboratory, but they cannot, even if they wished, carry out all the tests and investigations which should be made in their regions. The appointment of resident clinical pathologists in larger hospitals would seem to be the best way of solving this problem.

HUMAN CHORIONIC GONADOTROPHIN

In 1939 Astwood and Fevold¹ reported evidence which suggested that the anterior pituitary secretes three rather than two gonadotrophic factors. The first of these (FSH) stimulates the ovarian follicle to ripen, the second (LH), acting after and in conjunction with FSH, causes ovulation and initiates luteinization, whilst the third (luteotrophin) is said to be essential for the maintenance of the formed corpus luteum. As none of the pituitary hormones have been isolated, and as they are not available in adequate amounts for therapeutic purposes, various anterior-pituitary-like substances of chorionic origin are employed instead. Chief among the latter are equine serum gonadotrophin, which is follicle-stimulating, and human pregnancy urine gonadotrophin, the action of which has been the subject of controversy. In laboratory animals it is mainly luteinizing, but its effect on the human ovary is doubtful, and M. E. Davis² goes so far as to state that it "does not affect the human female favourably so that it is probably of no value in gynaecological therapy." This is an extreme view, but certainly human chorionic gonadotrophin when given alone has never been shown to possess the property at one time attributed to it of inducing ovulation and of initiating luteinization in woman. However, an investigation controlled by hormone assays and endometrial biopsies into the possibility of inducing ovulation in the human by a combination of follicle-stimulating hormone and chorionic gonadotrophin—the "one-two cyclic gonadotrophin therapy" of Hamblen and C. D. Davis³—gave promising results in a small series of cases. Other workers have failed to confirm these findings, but it is possible that the conflicting results may to some extent be due to variations in the dosage, purity, and potency of the preparations used.

Further light has now been shed on the subject by Brown and Bradbury,⁴ who describe a controlled study of the physiological action of chorionic gonadotrophin in normal women. In four cases the daily injection during the secretory phase of the menstrual cycle of amounts varying between 5,000 and 20,000 international units of the hormone produced a state of pseudo-pregnancy for periods of up to 19 days. Biopsy in these cases revealed the presence of decidual changes in the endometrium; the urinary excretion of pregnanediol continued beyond the usual life-span of the corpus luteum of menstruation; and in one case a well-developed and active corpus luteum was demonstrated at laparotomy on the fourteenth day of treatment. The onset of menstruation, however, could not be delayed indefinitely in these cases, bleeding occurring during, and despite, uninterrupted treatment. No explanation is offered for this last phenomenon, but it may lie in the fact that Brown and Bradbury gave the same dose daily in each case, whereas progressively larger doses may be required to maintain luteal activity. Once menstruation had begun the injection of the hormone was without effect. A more significant finding was that in five individuals treatment during the follicular phase of the cycle did not appear to hasten ovulation or the onset of luteal function. These observations strengthen the suggestion previously made that while chorionic gonadotrophin prolongs the activity of a pre-existing and functioning corpus luteum it does not by itself induce ovulation or initiate luteal activity. This view does not necessarily confirm the theory that there are three pituitary gonadotrophins, but if there are, then chorionic gonadotrophin resembles in its action luteotrophin

rather than LH. It also follows that it should be used when it is desired to enhance already established but deficient luteal activity. This is not to deny that chorionic gonadotrophin may have other uses. Thus it is sometimes of value in the treatment of metrorrhagia haemorrhagica where there is a complete absence of luteal activity, but in such cases there is some reason to believe that it controls the bleeding not by stimulating corpus luteum function but by depressing follicular activity.

THE TREATMENT OF CHOLERA

Hopes that the commoner sulphonamides or antibiotics would be active against cholera were disappointed; Bhatnagar and his colleagues,¹ however, have now produced a compound which in preliminary trials seems to have been much more effective. The first observation was that hexamethylene-tetra-amine in a 10% solution in physiological saline would kill cholera vibrios *in vitro* in less than half an hour. Crude compounds in which hexamine was linked with sulphanilamide were then prepared and in preliminary experiments gave promising results in animals and man. Later a condensation product containing two molecules of sulphathiazole and three molecules of formaldehyde was made. This compound has the formula $C_{21}H_{22}O_6N_8S_2$, but its actual constitution has not yet been worked out: for the present it is termed Compound 6257. *In vitro* bactericidal action on cholera vibrios was well marked in concentrations of 50 mg. per 10 ml., while with lesser concentrations above 5 mg. per 10 ml. there was bacteriostatic activity. The *in vitro* tests were confirmed in mice inoculated intraperitoneally with 2 M.L.D. of cholera vibrios. When mice were given 40 or 50 mg. in divided doses for two days prior to inoculation and then the same dose morning and evening for four days after inoculation there was complete protection if the drug was given subcutaneously or intraperitoneally. If given by mouth the drug saved only 10% of mice, presumably because of poor absorption from the alimentary tract.

Field trials were carried out in the Tanjore District of Southern India. The patients were for the most part undernourished women and children suffering from the effects of purgation, vomiting, and suppression of urine. A specimen of stools was first examined to establish the diagnosis, and the drug was then given in a dose of 6 g., followed 4 hours later by 4 g.—usually by mouth, though if vomiting were profuse the drug was administered per rectum. As a rule the total dosage was 28 g., of which 10 g. was given on the first day, two doses of 4 g. on the second day, and thereafter two doses of 1 g., morning and evening, for the next five days. Under this regime vomiting ceased and purgation was reduced within six hours: the urinary output was normal in about nine hours. Cholera vibrios were absent from the stools by the fifth morning.

So far 85 cases of bacteriologically proved cholera have been treated under field conditions in 27 villages, with a mortality of only 4%—in contrast to the usual mortality during the past seven years of 60%. No toxic manifestations have been seen even when as much as 50 g. has been given. Plenty of water, however, was drunk by the patients, and soda water when available. Although no details are given, it is said that the drug has been remarkably effective when administered prophylactically to contacts living in infected villages. If these results are confirmed a considerable advance in the chemotherapy of cholera has been made.

BITING MIDGES IN SCOTLAND

The minute black midges of the family *Ceratopogonidae* are very common in parts of Scotland during the summer months, particularly in the West Highlands, where the indignant sportsman frequently blames them for the lost salmon or the missed grouse. They do not transmit human diseases in this country, but most people who are bitten find the consequences very unpleasant. The irritation from the bite begins at once and may continue for several days; scratching aggravates it and may cause secondary infection. Nor do bites come singly: it is estimated that there are at least 50,000 active midges to the acre in areas where they are abundant. Investigations in the Trossachs at the height of the midge season (July–September) have given averages of 150 midges per person per hour. It is not surprising that agricultural work has been seriously impeded by midges in some places, and that the tourist traffic has suffered in the summer months.

A few years ago the subject of midge control was made the study of a special committee of the Scottish Department of Health. In 1946 an interim report was issued,¹ and recently a second report has appeared.² The most important item in the first report was the recommended use of the repellent dimethyl phthalate³ as a protection against midge bites. Biological data were few, and existing records showed the difficulty of direct control measures. The midges belong to the genus *Culicoides*, of which fifteen species were found; most of the trouble was clearly due to one species, *C. impunctatus*.

The recently published report contains details about the methods adopted to obtain further information about the life history of the midges. A trap was made in the form of a box, and in the bottom and sides of this small glass vials were inserted. Traps of this type were inverted over likely breeding-grounds, and the emerging midges were attracted by light into the glass vials. By this means some information has been obtained about the types of breeding-sites chosen by different species. Unfortunately relatively few of the most important species were caught in the traps, so that their preferences are still uncertain. When the breeding areas are known it may be possible to render them unsuitable or unattractive by drainage or similar operations. Alternatively it may prove feasible to attack them with insecticides. In the meantime sufferers will have to rely on the DMP (dimethyl phthalate) repellent. Further trials have confirmed its value. It can be applied to the skin—various formulae are suitable, but they must contain at least 40% of the substance. Skin applications only remain effective for a few hours, but more prolonged protection is possible by using wide mesh (4/16 in. \times 5/16 in.) veils impregnated with DMP. These are worn over the head and give protection without obscuring vision. If kept in a tin when not in use they remain effective for a fortnight.

COPENHAGEN INSTITUTE FOR HUMAN GENETICS

The foundation of an Institute for Human Genetics at the University of Copenhagen was first proposed by Prof. Oluf Thomsen in 1935. In 1938, with the help of a grant from the Rockefeller Foundation, the Institute was established, Prof. Tage Kemp being its first head. There is no doubt that had this department not existed it would have been necessary to create it in order to meet an urgent need. During the years 1929 to 1939 several eugenic laws were

adopted in Denmark. These dealt with sterilization, prohibition of marriage in certain circumstances, and abortion on eugenic grounds. The laws were skilfully framed and provided ample safeguards; they might well serve as a model for study should similar measures be contemplated in this country.

In a recent account¹ given to the Eugenics Society Prof. Kemp explained the working of the system and its practical results. It is not claimed that the new laws are having any great effect on the population as a whole. The aim has been different—the humane and intelligent application of measures to the benefit of the individual patient. To quote Prof. Kemp: "It is sometimes stated that the main purpose of eugenics is to spare society a good deal of expense. This, of course, is a great mistake. Negative eugenic measures are of an entirely medical character, aiming at the prevention of disease and misfortune." The average annual number of sterilizations was less than 20 in 1929–34, rising to 280 in 1935–9, and was no more than 350 during the years 1940–5. The use of these laws and the operation of the medico-legal machinery which they set up created the demand for genetic advice, and this the University Institute has been well qualified to supply.

During its brief life the research record of the Institute has been magnificent. In some ways the war almost helped research in Denmark: at least research was not interrupted to anything like the same extent as in many other countries. The Danes had no armed forces in which to serve. So far as they could they ignored the German occupiers and for long periods could concentrate on their work. We in this country can also be grateful because, presumably to annoy the Germans, English became the standard medium of publication. Apart from one volume in Danish (with English summary), all the wartime publications of the Institute are in English. From 1941 to 1946 ten large volumes of *Opera*² have appeared. Two of these are bound collections of reprints; the others deal with the following subjects: Graves's disease, achondroplasia, harelip and cleft palate, gypsies in Denmark, haemophilia, pituitary dwarfism in mice, deaf-mutism, and cancer of the breast. The attempt was being made, apparently with success, to ascertain and study every case of the rarer of the above diseases in Denmark. The material is carefully analysed and the conclusions fully set out. But what is even more valuable is that the individual case histories are given in detail, so that these volumes will remain an admirable source of material for research workers for many years to come. It was only after the war was over that the *Opera* became known in this country. Accordingly we propose to deal with some of them in a series of annotations. The first, on haemophilia, will appear in a later issue.

Prof. Warren H. Cole, M.D., F.A.C.S., Professor of Surgery in the University of Illinois, will deliver a Moynihan Lecture before the Royal College of Surgeons of England (Lincoln's Inn Fields, London, W.C.) to-day (Friday, April 2) at 5 p.m. His subject is "Repair of Strictures of the Common Bile Duct."

Dr. F. J. Nattrass, F.R.C.P., will deliver the Lumleian Lectures before the Royal College of Physicians of London (Pall Mall East, S.W.) on Tuesday and Thursday, April 13 and 15, at 5 p.m. His subject is "Clinical and Social Problems of Epilepsy."

MEDICAL SERVICES IN N.H.S.

Regulations governing the proposed general medical services have been issued under the title of National Health Service (General Medical and Pharmaceutical Services) Regulations. They provide for arrangements to be made by the Executive Councils with medical practitioners, the setting up of the Medical Practices Committee, and the terms of service for practitioners. They also prescribe the form of certificate to be issued by the Medical Practices Committee certifying that a transaction does not involve sale of goodwill.

Each Executive Council will furnish reports to the Medical Practices Committee before Dec. 31, 1948, and thereafter annually or more frequently if required, in order that the Committee may judge of the adequacy of the medical services in the Council's area. The Council must inform the Committee when a practitioner's name ceases to be on the medical list, because of death or any other cause, and it is empowered to advertise the vacancy in the Press or elsewhere.

If the number of applicants exceeds the number of practitioners required for vacancies notified by Executive Councils the Medical Practices Committee must consider the views expressed by the Council concerned, give any applicants an opportunity to attend before it or make written representations, and inform the successful and unsuccessful applicants of its decision. An unsuccessful applicant may appeal to the Minister, who may himself determine the appeal summarily or appoint one or more persons to hear it.

The Executive Council shall consult with the Local Medical Committee and constitute an Allocation Committee, consisting of equal numbers of persons appointed by the Council and Local Medical Committee and of a chairman. This committee will be responsible for administering the Council's "allocation scheme," by which it provides for, among other matters, the assignment of practitioners to patients and vice versa where necessary, and for placing a limit on the number of persons on a practitioner's list. This limit is normally 4,000, but when two or more partners practise together there may be 5,000 on any list provided that the average remains 4,000. A practitioner employing an assistant may take on 2,400 more patients for each assistant. The allocation scheme is subject to the approval of the Minister.

On the death of a medical practitioner (or on his name being withdrawn from the list) the Council may consult with the Local Medical Committee and appoint one or more practitioners to care for the deceased practitioner's patients. A person who no longer wishes to use the general medical services may get the Council to remove his name after 14 days. A person temporarily residing in a district who is not on a practitioner's list in that district may be accepted by a practitioner during his residence.

Distribution of Funds

The sum to be distributed for the remuneration of practitioners will be credited to the Local Executive Council, which will prepare a scheme for its distribution after consultation with the Local Medical Committee. If the two bodies fail to agree the matter will be referred to the Minister, whose determination is final. The provisions of the scheme are in any case subject to the approval of the Minister.

The first schedule of these regulations prescribes the terms of service for medical practitioners. "A practitioner is required to render to his patients all proper and necessary treatment." The scope of treatment required is that which does not involve the application of special skill or experience "of a degree or kind which general practitioners as a class cannot reasonably be expected to possess." Within these limits it includes the administration of anaesthetics and operative procedures. In the case of maternity medical services such treatment also includes antenatal supervision. In an emergency a practitioner must do whatever is best in the interest of the patient.

"A practitioner is required to attend and treat at the places, on the days, and at the hours to be arranged to the satisfaction of the Council" the patients in his care, but he may alter the time and place with the consent of the Council or, on appeal, if the Minister allows it.

"A practitioner is required to provide proper and sufficient surgery and waiting-room accommodation for his patients, having regard for the circumstances of his practice." He must allow any officer or member of the Council or Local Medical Committee to inspect his surgery or waiting-room at any reasonable time, on his receiving a written request.

A practitioner must visit a patient whose condition requires him to do so, and he must issue any certificates free of charge if they are reasonably required by the patient or required by an Act. A practitioner must prescribe for his patients on a form provided by the Council, and he is prohibited from giving the instructions "Rep. Mist."

A practitioner must keep records of the illnesses of his patients and his treatment of them in a form determined by the Minister, after consultation with an organization which in his opinion is representative of the general body of general practitioners. He must forward these records to the Executive Council when called for, and in any case within seven days of a patient's dying.

A practitioner must furnish in writing to the medical officer appointed by the Minister for the area any clinical information that he may require about a patient to whom the practitioner has issued, or declined to issue, a medical certificate. He must also allow the medical officer access at reasonable times to his surgery so that he may inspect the records, and he must answer any inquiries by the medical officer about prescriptions, certificates, or statements in any report made under the terms of service.

Partners and Assistants

A practitioner will normally treat his patients personally, but if he has a partner or an assistant one of these may treat his patients. Nevertheless the patient is entitled to require the personal services of the principal instead of the assistant's, unless professional duties or other reasonable cause prevent the principal from rendering them himself.

If the Executive Council, after consultation with the local medical committee, considers that a practitioner is not carrying out his obligations under the terms of service—owing, for example, to continued absence or disability—they may, with the consent of the Minister, notify persons on the practitioner's list that he is for the time being, in their opinion, not in a position to carry out his obligations.

The remuneration will be in accordance with the following scheme. There will be an annual payment of £300, provided that after a specified period the practitioner has a minimum number of patients specified by the scheme. There will be a capitation payment, payment in respect of temporary residents, payment for treatment given in an emergency of a patient not on that practitioner's list, a mileage payment, and payment in cases where the practitioner is required to provide the service of a second practitioner to administer an anaesthetic. Other payment will also be determined as follows. There will be an inducement payment made in areas unattractive to medical practitioners. A practitioner will receive a supervision fee for training an assistant under an arrangement approved by the Minister. Practitioners with obstetric experience will receive payment in respect of their providing maternity services. Practitioners will be paid in respect of the supply of drugs and appliances.

A report by the Liberal Party entitled *The Aged and the Nation* (8, Gayferc Street, S.W.1; 2s.) surveys the problems of old people and makes recommendations for consideration by the Party Assembly in Blackpool on April 22-24. The Report recommends improvements in pensions, housing, welfare services, homes and hostel medical treatment and administration of the services for the care of old people. It also urges that everything possible should be done to enable older workers to continue working as long as possible after pensionable age. The Report concludes that the medical profession should be encouraged to take an interest and undertake research in preventive and remedial treatment of the diseases of old age; that the aged should be admitted into geriatric departments of general hospitals, not into chronic sick wards; that long-stay residential annexes should be attached to general hospitals; and that senile dementias should receive treatment in special wards.

DISCIPLINE IN N.H.S.

Regulations entitled National Health Service (Service Committees and Tribunal) Regulations, 1948, have been issued. They empower every Executive Council to establish medical, pharmaceutical, and dental service committees, and a joint services committee. The medical service committee consists of a chairman and six other members, of whom three will be appointed by and from the lay members of the council, and three by the local medical committee. The joint services committee will have a chairman and eight other members, of whom two will be appointed by the medical service committee from their members, and two each from the dental and pharmaceutical services committees.

The medical service committee will investigate any complaint against a medical practitioner accusing him of failure to comply with the terms of service. The person making the complaint must do so within six weeks of the event which gives rise to it, unless there are exceptional circumstances preventing his doing so, such as illness. The committee will hear the proceedings in private and will draw up a report stating the evidence and its inferences, together with a recommendation about what action, if any, should be taken. It will present the report to the Executive Council, and the Council must accept as conclusive any finding of fact contained in it.

The Executive Council will send the Minister a copy of the report and a statement of its own decision on it, which may include action in one or more of the following ways: (a) If the Council considers that the practitioner's conduct complained of arises from his having too many patients, it may impose a special limit on the number of persons on his list. (b) The Council may recover from a practitioner by deduction from his remuneration or otherwise any expenses incurred by a patient owing to a practitioner's failure to comply with the terms of service. (c) The Council may represent to the Minister that an amount should be withheld from a practitioner's remuneration. (d) The Council may represent to the Tribunal that the continued inclusion of the medical practitioner on the medical list would be prejudicial to the medical services. Any party aggrieved by such a decision is entitled to appeal to the Minister, with the exception that no appeal can lie against the decision of a Council to make representations about the continued inclusion of a practitioner on the medical list.

If the Minister considers that the appeal is unreasonable, vexatious, or frivolous he may dismiss it forthwith, but he may not do so without an oral hearing if it is against a decision of the Council to take action according to (a), (b), or (c). The Minister may appoint one or more officers of the Ministry of Health, or other people (not more than three), for the oral hearing. His decision is final.

Advice on Fines

A medical advisory committee will be constituted to advise the Minister in relation to withholding money from medical practitioners when the terms of service have been broken. The breaches in question include failure to visit or treat a patient whose condition so requires and failure to supply necessary drugs. The committee will consist of the Chief Medical Officer of the Ministry of Health or his deputy, two other medical practitioners in the service of the Ministry of Health, and three medical practitioners selected by the Minister in rotation from a panel.

If after an investigation the Minister considers that orders for drugs, etc., given by a medical practitioner are excessive he may refer the matter to the local medical committee. The committee will furnish the practitioner with a statement of the matters of which an explanation is required. He may submit his evidence to them in person or in writing. If the committee considers that excessive cost is being incurred it will inform the Executive Council, the practitioner, and the Minister, and may add recommendations about withholding money from the practitioner. The practitioner can appeal against the decision of the local medical committee to the Minister, and the latter will appoint not more than three people (not officers of the Ministry of Health), of whom at least one will be a medical practitioner, to hear and determine the appeal. The Minister

may also adopt this procedure if he is dissatisfied with the decision of the local medical committee. Once it has been decided that excessive cost is being incurred the Minister may direct the Executive Council to withhold such sum as it thinks fit.

A similar procedure governs the investigation of alleged improper certification and record keeping. If the Minister considers that the practitioner has failed to exercise reasonable care in certification he may direct the council to withhold some amount from his remuneration.

AFTER-CARE OF MENTAL PATIENTS

Mr. Justice Birkett's Tribute

Presiding at the 68th annual meeting of the Mental After-Care Association on March 22, Dr. Henry Yellowlees, chairman of the Association, said that progress had been made in a number of branches of the work during the year, alike in the placing of patients in convalescent or holiday homes, the boarding-out of patients from mental hospitals, and the visits paid to patient homes. The little community of boarded-out patients was specially deserving of sympathy. These were people not in need of mental hospital care, but not well or strong enough to stand the rough-and-tumble of ordinary life. The Association was doing some of its most useful service in finding suitable homes for them.

Dr. J. S. I. Skottowe, medical superintendent of Buckinghamshire County Mental Hospital, said that not all discharged mental patients wanted what was commonly known as rehabilitation. Many of them just wanted to be left to go their own way in their own time, and slowly to take up the threads again. That they were able to do, by means of the Association, with the help of people who had some capacity for seeing things with the patients' eyes.

Sir Norman Birkett said that the work of a King's Bench judge was infinitely varied. He had to do with matters of dispute which covered the whole range of human feeling, and especially was this true, of course, of criminal proceedings. He had been greatly struck by the number of defendants who appeared in the criminal court of whom it had to be said on their behalf that much of their trouble and their conflict with the law had been due to mental abnormality. "When I hear, as I do hear in court, of the after-care which is available for them, I have often felt that it was one of the greatest qualities of our British people that there is no phase of social redemption or amelioration to which people will not be found ready and willing to give of their time, money, and service."

Mr. Justice Birkett recalled that at the Nuremberg trial one of the defendants was charged because he, as Minister of Health, responsible for the care and nurture of great numbers of people, had cultivated and ordered and carried out in respect of the old, the ill, and the mentally disabled, not measures of restoration or amelioration, but measures of destruction. "I could not help thinking as I sat there day after day listening to that melancholy record that whatever might be said of our own country—and critics are not lacking—at any rate there is one distinguishing feature, and that is that for those who are sick in body or mind there is a fund of compassion and pity which finds expression in societies like yours." It was not indiscriminate assistance which was afforded, but it called for the discerning mind and the qualities of insight and imagination, so that not only were material remedies applied but human sympathy given.

Delegates from Italy, Denmark, and Austria have attended a course in public health administration at Cardiff organized by the British Council with the co-operation of the Welsh National School of Medicine and the City of Cardiff Public Health Department. The visitors included Dr. G. Garaci, Permanent Under-Secretary, Italian Ministry of Health. There were lectures on the National Health Service Act, the Insurance Act of 1946, health administration in a city and a county area, the health of the school child, the mother and the infant, hospital services, health clinics, midwifery, the treatment of mental and nervous disorders, laboratory services, the treatment of venereal diseases, voluntary health services, and rehabilitation centres.

Reports of Societies

NUTRITIONAL STATUS IN BRITAIN

RECENT INVESTIGATIONS

A conference on "The Results of Recent Investigations of Nutritional Status in Great Britain" was held by the Nutrition Society at the London School of Hygiene and Tropical Medicine on March 13, with Dr. J. A. Charles in the chair.

Laboratory Investigations

Prof. J. R. MARRACK described the application of biochemical methods to nutritional surveys. These methods were used in the hope of collecting data free from local and temperamental bias and expressed in terms which had the same meaning all over the world. They should not only demonstrate the existence of malnutrition but also indicate the specific faults in the diet which caused this malnutrition. Before the investigator could interpret his data with confidence, however, he must make sure that his methods could be relied upon to give trustworthy results. The need for caution was emphasized during the survey of haemoglobin levels organized in 1943 by the Medical Research Council. Although an attempt was made to secure uniformity by asking all workers to use Haldane's visual method of estimation the agreement between results was poor. Thus a difference of about 7% was found between the mean values obtained by the two workers whose results showed the least variation among themselves, while there was a difference of 14% between the highest and lowest values of the worker whose results showed the widest variation. A careful sifting of the available evidence, however, indicated that in 1943 haemoglobin levels were no lower than before the war, while between 1943 and 1945 there has probably been some improvement, particularly in pregnant women and in school-children. The observation of lower haemoglobin levels in agricultural workers than in policemen or Civil Servants still presented a puzzling problem.

For vitamin C surveys most workers had used the "saturation tests" devised by L. J. Harris. According to this technique vitamin C status was measured by the rapidity with which ascorbic acid appeared in the urine after massive doses had been given under carefully standardized conditions. Harris and Olliver had established that vitamin C status varied consistently with the season. The lowest level occurred in spring, when few home-grown vegetables were available, but under normal economic circumstances the decline was arrested by plentiful imports of citrus fruits. Prof. Marrack considered that while our dietary restrictions had involved no risk of scurvy we could not be certain that health and efficiency had not suffered.

Surveys of vitamin A status by examinations of the plasma using the antimony trichloride method had at times given such inconsistent results that it was questionable how much trust could be put in them. Estimations of liver reserves post-mortem were probably more reliable, and suggested that so far as could be judged by comparison with data obtained by Moore in 1937 our vitamin A supplies had improved during the last few years. Thus in examinations of the livers of newborn babies Hoch and Marraek found much higher reserves than those reported by various workers before the war.

Laboratory methods for the estimation of the body's stores of several vitamins of the B group now seemed to be fairly trustworthy, but had not been used in any large-scale investigations. Surveys of vitamin D status by estimations of inorganic phosphates and phosphatase in plasma had also seldom been attempted, although in 1944 Graham found low values for phosphate in many Glasgow school-children. Estimations of the level of protein in the plasma could not be accepted as indicating the amount or quality of the protein available in the diet.

The first requirement for future progress was to check the reliability of biochemical methods. The second was to collect enough data in any one year to establish a "base line" against which future data could be compared. Finally it would be necessary to study for prolonged periods the health of groups

of subjects about whom biochemical data had been collected, so that the clinical significance of biochemical abnormalities might be correctly appraised. It seemed too much to expect that the effects of moderate changes in the diet would be apparent within a few months.

Anthropometric and Performance Tests

Prof. J. YUDKIN agreed that the establishment of "base lines" was one of the most pressing requirements in studying the effect of dietary changes on the health of the population. He considered that the problem could not be solved by the uncoordinated efforts of a few interested workers, and reminded the society that some years ago he had advocated the setting up of a National Nutritional Council.

In the interpretation of anthropometric data another difficulty had to be faced in deciding how far subnormality in height and weight could be correlated with malnutrition. Thus a child might be small for its age either through genetic factors or through falling short of the standards of perfect health. If genetic factors were ruled out it might be difficult to decide whether malnutrition was the cause of poor health or whether more importance should be attached to body hygiene, bad housing, lack of sleep, or other disadvantages which had poverty as their common origin. Fortunately these complicating factors could be minimized by studying groups of subjects of the same social class.

Many alternative forms of anthropometric measurement had been suggested, which perhaps implied that none had given complete satisfaction. Thus "static" data might be collected by recording body measurements and weights on a single occasion. These data might be related, simply to age, or various devices may be employed with the intention of emphasizing the effects of malnutrition. Sitting height, for example, might be considered to be more significant than the standing height, or the Tuxford index relating weight to height might be calculated on the assumption that malnourished subjects were lighter than well-nourished subjects of the same height. "Dynamic" data might be obtained by studying gains in height or weight over a given period, and for this purpose the Wetzel grid was useful.

Anthropometric data collected by Prof. Yudkin, mainly at Cambridge, indicated that weights and heights were slightly lower in children from families with low incomes than in children from families with higher incomes. In the same income groups children were larger in small families than in large families. Data collected by Milligan and Lewis-Fanning indicated that there had been an improvement in the height and weight of infants in Glossop up to 1944 as compared with before the war.

Since the ultimate effect of malnutrition was disease it was highly desirable that clinical methods for the diagnosis of malnutrition should be devised. Apart from the recognition of gross signs little progress had been made in this direction. Thus the system used in the school medical service of recognizing four grades of nutritional status—excellent, normal, fair, and poor—had given inconsistent results when the same group of children had been examined by different doctors, or even on different occasions by the same doctor. Tests of strength by the dynamometer and other means had given encouraging results, but must obviously be used with discretion. Jokl had claimed that while well-nourished children could beat poorly nourished children at putting the shot or sprinting 100 yards the situation was reversed in a "middle distance" race of 600 yards.

Clinical Surveys

Dr. H. M. SINCLAIR criticized methods, such as those used by the Board of Education and the Ministry of Health, in which general development, posture, and muscular strength were taken as indications of the state of nutrition at the time of examination. Physical development depended upon both genetic factors and past nutrition, and signs of current dietary deficiency were by no means confined to subjects of poor physique. A rapid examination of the subject for signs of malnutrition, as conducted by Dr. Sydenstricker during his visit to this country in 1942, was less open to error. After inquiring into the medical history of each subject the doctor should seek information on certain specific symptoms, including

change in body weight, muscle pains or cramps, sore tongue, sore eyes, rapidly failing vision, weakness or fatigue, nycturia, and diarrhoea. Information about menstruation and lactation should also be obtained if relevant. The skin, hair, nails, tongue, gums, mucous membranes, and eyes should be carefully inspected, and note should be taken of any general abnormalities such as obesity, thinness, active rickets or osteomalacia, oedema, paresis, or tenderness of the muscles. In examining large groups of subjects the use of the "Hollerith" punched card system was a great convenience.

In the interpretation of the results of clinical examinations great caution was necessary. Thus folliculosis might be caused by deficiency of vitamin C or of vitamin A, but another possible cause was shortage of soap. Denudation of the filiform papillae of the tongue was much more common in those with dentures than in those with natural teeth. In the diagnosis of malnutrition therefore it was necessary to take into consideration all information which might be gained from the dietary history, somatometric data, and biochemical estimations. It was equally essential to decide on the nature of the deficiency causing malnutrition. Nothing could be gained by attempting to grade the severity of malnutrition on a general basis; a severe case of rickets could not be compared numerically with a case involving mild deficiencies of several nutrients.

During the past several years there had been a marked increase in the rate of growth of children, although in England and the U.S.A. the adult male height had remained unchanged. It had not been shown that this increase in growth rate was necessarily advantageous; it might indeed be undesirable since the long time taken to reach maturity was characteristic of the human genus. Biochemical studies by the Oxford Nutrition Survey had indicated considerable differences in the vitamin contents of the blood plasma at different times of the year and in different parts of the country. Thus women in an Oxfordshire village examined in September, 1942, gave a mean of 0.92 mg. of ascorbic acid per 100 ml., as against 0.1 mg. for women in Accrington examined in January and February of the same year. The mean level of vitamin A in the plasma of Oxford undergraduates in November, 1943, was 132 I.U. per 100 ml., as against 64.5 I.U. for factory workers near Oxford in November, 1942.

Discussion

Dr. C. C. UNGLEY stressed the need for combining clinical and biochemical observations in the examination of patients suspected to be suffering from malnutrition, and illustrated his arguments by describing two cases in which deficiency of vitamin B₁ was diagnosed and treated. Dr. E. R. BRANSBY considered that the heights and weights of groups of children were reliable indices of their nutritional status, provided genetic factors did not interfere. He hoped that a target would be set to bring the physique of poor children up to the level of those in better economic circumstances.

Dr. M. PYKE showed diagrams, prepared by the Ministry of Food, which indicated the supplies of nutrients available in Britain during recent years. He asserted that there was no evidence of any serious deficiency. Points of interest were the seasonal variation in the supplies of vitamins C and A, which reached their lowest point in spring, and also the marked rise in the iron intake which occurred in 1945 on account of a temporary raising of the extraction rate of flour to 90%. Dr. E. H. M. MILLIGAN spoke on the value of performance tests, and considered that they should not exclude the factor of will power.

Dr. A. P. MEIKLEJOHN said that in poor families, particularly with large numbers of children, malnutrition might result from lack of time and facilities to prepare nourishing meals even when the foods were available. Dr. S. K. KON described a survey of the nutrient contents of human milk: an increase in the vitamin B₁ content had been observed which could be correlated with the introduction of flour of high extraction rate. Miss M. ANDROSS presented data comparing the food intake of students in a Glasgow hostel in 1935 and 1948. There appeared to have been a slight fall in the consumption of protein, but a surprising rise from 78 g. to 101 g. daily in the consumption of fat.

Dr. R. B. HAWES summarized the day's proceedings on behalf of his colleague Dr. H. E. MAGEE, of the Ministry of Health.

He regretted that none of the speakers had provided any substantial information on the present nutritional status of the country, but had focused their attention mainly on the discussion of methods. In his opinion the severe criticism of the methods used by the Board of Education was unjustified.

Rh FACTOR

At a meeting of the Medical Society of the L.C.C. Service at County Hall on March 5, Dr. E. N. ALLOTT, of the Lewisham Group Laboratory, read a paper on the rhesus factor and blood transfusion.

There had been a great increase in blood transfusion in recent years, and a lot of transfusions, he thought, were unnecessary. Rh tests should always be done before transfusing a woman of child-bearing age. The dangers of giving Rh-positive blood to Rh-negative female patients were just as great as those of ABO incompatibility. In a large proportion of Rh-negative patients transfused with Rh-positive blood antibodies were produced.

He had records of 38 patients whose first affected pregnancy followed transfusion with blood of unknown Rh type. Of these 38 patients 26 received transfusions before 1944, when the significance of Rh groups was perhaps not sufficiently widely recognized. But 12 of the transfusions had been given since 1944, and were inexcusable. Only 4 were given for medical and surgical conditions not associated with obstetrics and gynaecology. Of the 38 patients 8 had never been pregnant or had only had one miscarriage before transfusion. Subsequently they had had 11 pregnancies: 3 children were living and the other 8 infants died or were stillborn.

In the last three years he had come across 9 reactions due to Rh-positive blood in Rh-negative patients. Two at least of the transfusions, including that in one of the two fatal cases, gave rise to no abnormal symptoms while the blood was being given, but were followed by complete urinary suppression. The others all had reactions of varying degree, followed in many by more or less complete urinary suppression. At least 6 of the 9 transfusions were unjustifiable.

Erythroblastosis Foetalis

Dr. C. A. HOLMAN, assistant pathologist at the Lewisham Group Laboratory, reading a paper on the treatment of erythroblastosis foetalis, said that it was important to recognize isoimmunization early in pregnancy and to do routine Rh tests on all pregnant women. The serum examination should be repeated regularly in all Rh-negative women and others with suspicious histories throughout the last two months of pregnancy. If this was not possible, the serum should be checked at about the thirty-fifth week. Known cases should have regular estimations of the serum titres. If there was a significant rise in the titre—and he considered a fourfold rise a danger signal—or if the infant's movements became feeble, induction of labour should be considered at once. In any case induction should be undertaken at 36 weeks, as the last month *in utero* was the most dangerous.

Cord blood should be collected from the newly born infant immediately after delivery for a direct Coombs test and a haemoglobin estimation. If the former was positive, a replacement transfusion via the umbilical vein should be proceeded with at once, using at least 1 pint (568 ml.) of compatible Rh-negative blood. This was the simplest and safest way of treating infants suffering from erythroblastosis; it prevented any gross anaemia and minimized the jaundice. It did not, however, offer any protection against kernicterus. If the Coombs test was negative, transfusion was not necessary, but the child should be watched.

Dr. Holman described the technique of replacement transfusion in detail, and pointed out that in suspicious cases everything should be ready before delivery for replacement transfusion, and the operator should be prepared to spend several hours doing the transfusion. As a result of replacement transfusion with a pint of blood about 80-90% of the infant's cells were removed and replaced by non-reacting normal adult cells. If the disease was recognized twelve hours or more after birth, when replacement transfusion by the

umbilical vein was no longer possible, it was necessary to watch the infant's haemoglobin. If this fell rapidly on the first or second day a transfusion should be arranged at once; otherwise it was advisable to wait until the haemoglobin had dropped to about 50% and then give about 250 ml. of Rh-negative blood by slow drip. A transfusion of this size would carry the infant over the period during which its initial blood cells were being destroyed and would maintain it until these had been replaced. All infants treated in this way should be followed up and given iron and ammonium citrate as required, if necessary until fully weaned.

Immediate and Delayed Jaundice

Dr. A. G. SIGNY, of St. Mary Abbots' Hospital Group Laboratory, said that cases of jaundice after transfusion might be immediate or delayed. The immediate ones were part of a more general haemolytic shock associated with destruction of the donor's cells and, very occasionally, of the recipient's cells. He recalled Mollison's report to the Medical Research Council describing the investigations which should be undertaken when such cases occurred. He pointed out that the duration of the jaundice would depend not only on the degree of haemolysis but also on the extent of the liver damage. He described the method of treatment by immediate alkalization. Discussing delayed jaundice, he reviewed many reported cases, including the series followed up by Janet Vaughan and her colleagues. He also mentioned some cases he had seen, and described the clinical, biochemical, and histological features, which were on the whole identical with those of infective hepatitis except for the longer incubation period and the severer type of disease with a longer period of recovery time and a higher proportion of deaths. He stressed the increased risks when serum or plasma was used as against those when using blood.

On the question of general prophylaxis there were many measures which were obvious, such as not using blood from donors who had recently been jaundiced or in contact with cases of jaundice. Treatment of the plasma had so far failed to remove the icterogenic agent, but he thought that the advice of Makari should be followed and that a routine flocculation test should be done on all blood donors at the same time as Wassermann and grouping tests. No blood showing any change in its colloidal gold reaction or other flocculation tests should be used for transfusion.

NEURITIS

A discussion on neuritis took place at a meeting of the Hunterian Society on March 15, with Mr. A. E. ROCHE presiding.

Dr. PHILIP ELLMAN said that neuritis was a term loosely used, a dumping ground for many things from neurosis to neuralgia, even including the shooting pains of tabes. He discussed localized forms, in particular sciatica, brachial neuritis, and the so-called costoclavicular syndrome. The principal causes of polyneuropathy could be classified as infection, chemical agents, and metabolic deficiency. Fibrositis, like neuritis itself, was a term which had been applied to innumerable maladies showing a common symptomatology, but in spite of the valuable work of Copeman and others its aetiology and pathology remained obscure. In his general conclusion Dr. Ellman emphasized the dangers of surrendering judgment to the fascination of a name—dangers nowhere more apparent than in this field.

Dr. ALDREN TURNER said that neuritis in the sense of inflammation of the peripheral nerves seemed to be rapidly losing ground as an accurate diagnosis. Actual inflammation of the peripheral nerve was uncommon; in the majority of cases there appeared to be a metabolic or degenerative process at work rather than an inflammatory one. He discussed three conditions which had been "rescued" comparatively recently: (1) lateral prolapse of the intervertebral disk; (2) axillary inlet syndrome due to mechanical compression, albeit intermittent, of the nerves and great vessels as they passed through the neck to the axilla, and (3) severe pain round the shoulder, followed by a palsy. Dr. Turner described the favourable clinical results in 46 cases of prolapse of the cervical disk treated conservatively by means of rest in bed, four or five pillows behind the

neck, a sling for the arm, and a mild analgesic. The third condition he had mentioned might possibly be a true neuritis. Pain was felt around the shoulder girdle and radiating down the arm, lasting for a few days or even two or three weeks, and followed by a certain amount of paresis. There was no fever or constitutional disturbance. His observations on this condition were based on 136 Army cases. He did not know the aetiology and pathology, and a suitable name was lacking. The terms "localized neuritis of the shoulder girdle," "infective neuritis," and "acute brachial neuritis" had all been used, but a non-specific name seemed to be preferable.

Surgeon's Point of View

Mr. DUDLEY BUXTON said that "martyrs to sciatica" were no longer to be found, but a considerable number of people still told their friends that they had "neuritis." He had seen patients labelled cases of neuritis when they had thromboangiitis obliterans. Surgical treatment should be considered when the nerves were irritated, when there was compression, and when there was tension. The costoclavicular syndrome had been dealt with surgically—an important advance was the realization that a cervical rib or a fibrous band was only part of the causation.

Dr. FRANK COCKSEY agreed that rest was the key to treatment for the relief of pain, but rest might not always be sufficient, and three further methods presented themselves, namely, heat, ultra-violet light, and ionization. He spoke in particular of the value of dark heat and moist heat. Radiant heat should be used with the lamp further away than usual, and the time of application should be short. He usually started with applications of five minutes' duration, increasing gradually. Diathermy was useful for neuralgia or neuritic pains arising from osteoarthritis of the spine.

Dr. KENNETH MCFADYEN had heard with surprise that one of the best remedies was rest, because as a general practitioner, when sending patients to the physiotherapeutic department of a teaching hospital, he had learned from them afterwards that they had done exercises. With regard to moist heat, he wished that some people in the big hospitals would themselves learn, and teach others, how to make a really good linseed poultice.

Dr. WILFRED HARRIS, Dr. F. WRIGLEY, and Mr. DICKSON WRIGHT joined in some further discussion. Dr. W. S. C. COPEMAN said that twenty years ago, when he was registrar to the late Sir William Willcox, who was also interested in this subject, he congratulated his chief on one occasion on a very learned lecture he had given at St. Mary's, and Willcox said in reply, "Well, you know, there are a lot of eases with this sort of thing, but the cure is the same in all of them," and after his interrogator had waited expectantly, Willcox added, "Six weeks." The theory of this subject had advanced more rapidly than the therapy.

Delegates to the Scottish Council of Social Service's week-end conference in Edinburgh recently heard Mr. J. Callan Wilson, of the Department of Health for Scotland, give some reasons for the introduction of the National Health Service. Hospital organization, he said, had grown up without plan or system. Some hospitals, dealing mainly with general medicine and surgery, were voluntary and supported by subscriptions, donations, flag days, and charitable efforts of various kinds. Others, such as infectious-diseases hospitals, sanatoria for tuberculosis, and maternity hospitals, were run by local authorities. There was no cohesion; existing services were not comprehensive and there was unnecessary overlapping and competition. Moreover, the provision of special services, such as for orthopaedics, was totally inadequate. The absence of regional organization had confined the university influence and concentrated specialized skill in small groups for teaching hospitals. The increasing cost of hospital service was another factor to consider. Exchequer assistance was inevitable, therefore control by the Exchequer was unavoidable. Discussing the family doctor, Mr. Wilson said that to-day there was an organized public service providing a family doctor for only about half the population. There was no provision for the families of dependants of insured persons—a serious gap which must be bridged. Most difficult of access to people of moderate means to-day were the consultant and specialist services. The person who could pay a fee for consultant advice had no difficulty, but the person who could not afford a fee could have access to consultant and specialist advice only through the out-patient departments of the voluntary hospitals. Arrangements of this kind were not well organized at present.

Correspondence

Consultant Leadership

SIR.—Mr Reginald Payne's contention (March 13, p. 514) that consultants were bitterly disappointed that they had received no guidance or leadership from those in high authority, who had been elected to represent them, is justifiable and unanswerable. For some reason these leaders appeared to be unwilling to commit themselves to any declared policy or public pronouncement. The long and disturbing silence going on from month to month left the consultants baffled and disoriented and raised doubts and suspicions in the mind of the general practitioner. How comforting and encouraging it must have been to the Minister to feel that no breath of criticism or threat of battle need be feared from those in high representative office in the largest medical centre in the British Isles. What a contrast was provided by the declaration issued by the Royal Faculty of Physicians and Surgeons of Glasgow on March 3, 1947, which they reaffirmed on Jan. 5, 1948 (see *Journal*, Feb. 7, p. 257). There was no ambiguity in their memorandum; it was bold and constructive, and it was crystal clear which side of the fence they were on. They rejected totalitarian dictation from a politician.

One heard of members of the staffs of some hospitals receiving payment in the interim period, and some not; the payment, ostensibly, came from the boards of management. This is no criticism levelled at those who received it; there had been no declared policy, and payment was said to carry no liability. Hospitals and institutions were receiving financial help to a hitherto-unheard-of extent, with the sky as the limit. We heard vaguely of large grants from the Ministry being made to representative and influential bodies. It is difficult to accept all such and then vilify the Minister; whether they incur a liability or not is not the point at issue: their reception must exert an influence (in the interim period), and the impression was left that a rather insidious form of bribery was raising its head.

The Minister was quick to see that a wedge might be successfully driven between the consultant and the general practitioner, and he may still covet that hope. Not until 800 consultants met in London of their own free will, with no coercion from the B.M.A. or encouragement from any corporate body, and most emphatically expressed their individual refusal to work the Act as constituted—then, and then only, did the general practitioner begin to look upon the consultant as an ally. And is this suspicion entirely allayed yet? I doubt whether it will be until an unmistakable lead is given from representative consultant authority. For the silence is still unbroken and threatens to remain so. 2,600 Fellows of the College of Surgeons may know where they stand individually; in fact the great majority have instinctively realized the danger of investing a politician with the immense dictatorial power which this one, and possibly others, even irrespective of party, intend to assume, but do they know, or does the Minister know, where they stand collectively as a representative body?

Is it not essential that those who are elected to high office in the near future as representing the various consultant branches have openly declared their intention of calling for the repeal of such an Act, or insisting on the deletion of all clauses which the profession cannot tolerate? Such representatives should have no personal axe to grind and no fence to sit upon.—I am, etc.,

London, W.1.

A. R. DINGLEY.

What is Professional Freedom?

SIR.—We doctors are fighting to retain our professional freedom. If we remain clear-headed and united we are bound to win by a comfortable margin. But how many of us are clear that *professional freedom is a compound of civil and political liberties*? A brief glance at the following quotation from C. D. Hardie's *Background to Modern Thought* (Thinker's Library, 1947), should satisfy the doubters, if there are any. (Hardie is professor of education in the University of Tasmania, not a medical man. It is interesting to note how many of the funda-

mental freedoms we are determined to retain are basic to truly democratic citizenship.)

"Under the idea of civil freedom can be listed at least the following: Freedom (1) from fear as to my personal safety; (2) from fear as to the safety of my property; (3) to move when and where I please; (4) to speak and write what I think; (5) from fear of unjust imprisonment; (6) from fear of economic insecurity; (7) to worship as I please; (8) to assemble with whom I like. Under the idea of political freedom I should be inclined to list: Freedom (1) to advocate amendment of the laws; (2) to criticize policies; (3) to vote by secret ballot; (4) to hold office in government if selected by one's fellows."

He goes on: "It is . . . quite impossible that all of these freedoms will ever be obtained." (The complete attainment of one must sometimes interfere with the complete attainment of another.) "Yet most people at most times have, with sound instinct, striven for as much as possible of each one. And here, it seems to me, we come to the chief contribution which the English-speaking peoples have made to civilization. Ever since the thirteenth century, when the foundations of both civil and political liberty were laid, the English have been in the forefront of the struggle. It is unfortunately true that they have struggled much more for themselves than for others . . . but it seems probable that they are beginning to realize that when liberty is threatened in one place it is threatened everywhere." (My immediate comment on this last observation is a very simple one. Are they?)

It is up to us doctors, then, to get the people to see—so far as they can be got to see—that the present threat to *our* freedom is also a threat to *theirs*. But even if we fail in this, we still know we are right; and by simply standing firm we can win—without the public's support. In this contest, of such vital importance to the whole country, what truly lucky people they—and we—are!—I am, etc.

Glasgow.

J. INGLIS CAMERON.

A Phoenix Act Needed

SIR.—Touching general practice, the French "Assurance Sociales" scheme is ably outlined by Dr. J. Delafresnaye (March 13, p. 519). After spending some two months in its study I was convinced that it functions no less smoothly as regards hospital and consultant services.

I am given to understand that New Zealand has operated for many years past a fundamentally similar scheme. A comparative study would be illuminating, for the Dominion appears—from many critical accounts—to have failed lamentably where France has succeeded so well—i.e., to promote specialization, postgraduate study, and research.

I cannot speak with knowledge of New Zealand's alleged failure, but am sure that France's admitted success is due to the fact that:

(1) Its basic motive was a genuine desire to promote health. *Incredibile dictu* for a Government-sponsored scheme, its inception was unconnected with political theories and intrigue. (The advance of Communism in the country can be fully explained without: praying in aid hospitals or doctors. The latter are *not* State-controlled: they are in full possession of their liberties.)

(2) The doctor-patient relationship is secret, inviolable, indeed unaffected. The "complicated administrative machine" of which Dr. Delafresnaye speaks is a lay accountancy which minds its own business and conducts it well. It is not unduly expensive.

(3) The 20% deduction just happily suffices to prevent abuse of the system by patient or doctor without penalizing the sick. A very poor or chronically ill patient might find his 20% contribution a burden: public funds from other sources can deal with such a totally exceptional case. *Everyone is 20% a private patient*—at once a status and a delicate tribute to private enterprise. As far as the doctor is concerned, he is 100% private.

I have long hoped we may eventually devise a counterpart which need not slavishly follow either France or New Zealand, and that is why I want to know where New Zealand went wrong. I suspect she concentrated too much on the G.P., just as we did in 1911, forgetting that the G.P. is nothing without his specialized colleagues or they without him, or either without a hospital.

The scheme of 1911 was a century behind the times even then. It is something "to provide the breadwinner with a doctor," but not much when you reflect that the breadwinner is on the whole the least expensive member of the family in regard to medical services, and the "doctor" usually a consultant—now a squad of consultants where the illness is of the more disabling type, physically or financially speaking.

I admit the employment of women and the later extensions to N.H.I. have tended to enhance its value (so, very greatly, have the dental benefits, where the French "20% principle" seems to be recognized but less equitably applied). But on the whole I am sure that N.H.I. has failed wretchedly. On a hundred counts it could be indicted apart from a tendency to laxity in certification. I am sure the Government tacitly admit its failure and that the N.H.S. has been devised in great part to abolish the panel without loss of face.

If that view is correct, we are likely to be confronted with a health service that possesses none of the advantages of the French plan and may be a thousand times worse than the New Zealand scheme. Meanwhile the abolition of the panel is a moral triumph (I wish I could see how it will work out in practice) for the opponents of Lloyd George's Act 37 years ago. The majority of the medical profession in 1911 said it would not work, and, while they had to endure it for a season, they proved right in the long run. It remains for those of us who oppose the Act of 1948 to do even better—not to submit to its yoke even for 37 minutes.

I have never understood the eternal moan, "We gave way in 1911—we shall do it again." It is a parrot's repetition and it is false. The death of the panel is a colossal triumph: we can create a new entity phoenix-like from the ashes, but we shall have to nip in pretty smartly on July 5, 1948.—I am, etc.,

Stratford-on-Avon

PETER PARRY.

The New Despotism

SIR,—In following the correspondence arising out of the controversy over the proposed N.H.S. I have been struck by the failure, if not to appreciate certain points, at least to stress them adequately. As I see it, the first point is that the Ministry concerned not only will not give way but *cannot* give way on any essential point, and this for a simple reason which should be obvious to all and which, briefly, is this: the Government is *not* primarily after the doctor but after the working man, and we are but an unfortunate small obstacle on the way.

The Government has made itself responsible for all treatment and maintenance thereof and for the payment of all sick and compensation benefits. Under the Act as it stands the costs of treatment maintenance and the payments of benefits, if made on anything like a fair basis, will manifestly bankrupt the Ministry in a very short time, and the Treasury will see to it that this does not happen. It is time that someone put the thing into plain language: we all know that the collection of publicly allocated money by potential beneficiaries can be (and occasionally has been) something of a ramp. We know equally that it is a matter of the most extreme difficulty to devise methods of safeguarding such funds which are not readily capable of the most deadly abuse. We know as well (we are even told so by the Government) that there is too much absenteeism. We are told also that the Minister must obtain control of certification. I submit that there can be no one who is such an imbecile as not to know perfectly well just what this means. Let us then have it in good plain English and without ambiguity: the Government's real intention is to keep the working man at work to the maximum possible extent and to deny him absence benefits except in those cases in which denial will be obviously impossible or blatantly scandalous. Anything else on the arithmetic of the Act means a scheme bankrupt before it is well started. There can be no other explanation for the implacable attitudes of all the Ministers who have been concerned, for the denial to us of the most elementary rights of conscience, and for the revival of what promises to be a very good parallel to the Star Chamber.

The most striking thing about this proposed abrogation of civil rights is that it is not political in the "party" sense. The Government, for reasons obvious to the point of blatancy, is making a party stunt of the present struggle, but there seems to be no one to point out the vital fact that this measure is *not* a party matter. It was worked out and sponsored by another party, and one of our most unimpeachable legal authorities (Hewart) has warned us of the implications of this kind of legislation.

Another fact has become clear, I think, to all, and let us make no mistake about the matter. The Government will use every means in its power to crush us and to make us instruments of its oppression. It is not so long ago, even in England, that free men have lost their all for the freedom of their consciences. Let us

remember, too, that a government bent on oppression can very soon create powerful instruments for its purpose should the occasion arise and we need not look very far back into our history to find illuminating examples. Contemporary examples abroad need no stressing.

What, then, are we to do? I suggest that, whatever the cost, there is but one course open to us and that is resistance to the uttermost. To do anything else is to become something unnamable and to stink in the nostrils of every decent civilized man along with those who knuckled under to Laud, Jeffreys, Hitler, and their kind—past and present.

Our weapons are as obvious as they are potent. First let us realize that, if all of the enormous majority of us who are against it refuse to work the Act and are but consistent, not only do we win but we take from our opponents one of their most powerful weapons, because we make it impossible for creditors to foreclose on us to recover payments temporarily suspended (the creditor cannot realize on the security—i.e., the practice—because there is no purchaser). The one obvious possible purchaser *can be barred in the interests of the creditors* by a very simple manoeuvre. We can, if we go about it the right way, and keep an eye on certain possible eventualities which will be well known to our legal advisers, lead these interests to give us their very powerful backing for their own sakes. Secondly, and most important of all, if we can force on to the realization of the working man that this Act goes far beyond any consideration of mere party politics and is directed primarily and principally against him, the battle is automatically won. These men through their political machinery and directly can, by their voting power, turn this Government any way they like.

A simple, brief, and trenchant statement of the threat to them and, indeed, to everyone should turn the scale easily enough. It must be brief, it must be simple, and above all it must be put in good, plain, hard-hitting English. There is no time to be lost. I may add that, as I have no practice, I am interested solely as a question of freedom and liberty, but, nevertheless, like all those in my position who voted "against," am none the less interested.—I am, etc.,

Sunderland.

A. KEF H.A.S.

Way of Freedom

SIR,—Persons may be divided into two classes: (a) dictators and would-be dictators whose chief ambition is to attain increasing power over other persons and whose highest good is freedom without responsibility, and (b) those who are *not* so minded. The latter have their choice of two policies: either (1) spoon-feeding on condition that they accept the domination of men of dictator mind, or (2) freedom to act, to choose, or to refuse with the attendant responsibilities.

Great numbers of persons are now choosing to be spoon-fed. They are attracted by the proposition of everything being made safe for them from the cradle to the grave. This is assured to them so long as they lick and stick the required stamps and do exactly as they are told. All they want of freedom is freedom to choose the apparently easy way.

As the plebiscite figures show, doctors, by an overwhelming majority, have rejected spoon-feeding and have chosen the way of freedom and its responsibilities. They recognize that men are by nature free, and that in defending their freedom they are defending their life. That is the policy of those who solemnly and honestly have voted with the majority. We have put our hand to the plough. For us in truth there can be no looking back—not even in the presence of what looks like defeat, if this should come. We have stated where we want to go. We now want leadership, and we are looking to the executive of the Association for guidance to the best means to attain our objective. It is for this purpose that we are associated. If at this crucial moment the executive fail to give the leadership which the situation demands, or if, leadership being given, the members fail to follow, the fruits of association must inevitably be lost and the Association as a whole correspondingly discredited.

Finally, if there are those who are still undecided, one would say to such: "Either choose now to join the fight for the preservation of our traditional liberties or separate yourselves from those who have made this choice and attach yourselves openly to whichever section you belong—the dictators or the material upon which the dictators work, namely, the spoon-fed masses."—I am, etc.,

Bewley, Kent.

The Successful Treatment of FIBROSITIS and certain cases of RHEUMATISM with NOVUTOX

A mass of evidence has accumulated to show that the treatment of Fibrositis and certain cases of Rheumatism with Novutox injections provides not only complete restoration of function with immediate relief from pain, but also, in many cases, early recovery.

Interested members of the medical profession are invited to write for a copy of a Thesis on "THE INJECTION TREATMENT OF FIBROSITIS—with special reference to: Lumbago, Muscular Rheumatism (Acute and Chronic), Muscular Pain (of Traumatic Origin)."

NOVUTOX is available in:

2-oz. and 20-oz. Bottles: 1%, 1% and 2% Solutions.
Boxes of 12 x 2 c.c. Ampoules: 1% and 2% Solutions.

Each c.c. of Novutox 2% contains 0.02 gm. ethocaine hcl., 0.00002 gm. epinephrine and 0.00002 gm. capryl hydrocupreinotoxin hcl. Other strengths of Novutox contain these elements (with or without epinephrine) in varying proportions.

Safeguarding Private Practice

SIR,—It was a pleasure to read Dr. W. Reginald Wilson's letter (March 20, p. 565). It should cheer him to know that the principle that "there should be no penalty to either doctor or patient who remains outside the National Health Service" was carried with very little opposition at the S.R.M. on March 17. For the sake of those who are not aware of all the motions that have been passed by the Representative Body I would point out to my colleagues who are in doubt as to the B.M.A.'s policy that the representatives only gave way on the 100% issue (after the discussions with Mr. Willink) provided that "any member of the community, whatever his income, should be entitled to obtain his medical service in part or in whole privately, as, for example, by grant-in-aid provision" (S.R.M., 1945). Further motions supporting "contracting-out" were passed at the A.R.M., July, 1945.

In May, 1946, the Council, in its report on the N.H.S. Bill, stated: "The freedom of the citizen requires not only that he should be free to obtain his medical care privately, but that the arrangements should be such as not to penalize him or his doctor if he does." In July, 1946, the A.R.M. passed a further motion urging that the financial and administrative arrangements should be such that neither doctor nor patient should be penalized if he chooses to remain outside the national service. This is the policy of the B.M.A., and it is of the utmost importance that there should be an absolute refusal to yield on this vital issue.

The representatives have continually reiterated their request that private practice should be effectively safeguarded. Should it be found that after all it is not possible to give effective safeguards to prevent a State monopoly, then it is time we reverted to the policy that: "There is no need for the State to provide a service for those willing and able to provide it for themselves." Perhaps this is what the Representative Body meant when on March 17 it passed the motion instructing the Council, in the event of a deadlock with the Government, to draw up and submit to the profession an alternative scheme based on the 1944 A.R.M. motion by Marylebone.—I am, etc.,

Dorking, Surrey.

CYRIL E. BEARE.

Ownership of Goodwill

SIR,—You have published so many excellent letters that most of the ground is covered and one can only underline what others have said and what you have said in your leading articles.

The letter from Dr. R. Preston Hendry headed "The Minister's Confusion" (March 20, p. 561) is most forceful, and I heartily agree that it is a most pernicious lie to say the "patients are bought and sold." Such a statement can hardly be made in ignorance—although it would seem that the opposition as well as the public are inclined to agree.

The hardship of buying a practice or partnership has been grossly exaggerated. Surely it is the easiest and safest way for a young man to begin practice. At two years' purchase he gets a 50% return for the money invested and he still has his practice, which he can sell again when he so desires, and at a higher price if he has improved it—a point which is so often forgotten.

As your correspondent points out, the right to buy and sell should be firmly retained because it solves so many other problems and is therefore a corner-stone in our opposition to the Act—freedom is thereby retained, and this is the only way this priceless principle can be retained. Indeed, it might be said that this right to buy and sell, if granted, would almost make the Act acceptable to us and workable. On the other hand, if we lose this right it is difficult to see how we can avoid a full-time State service.

How about concentrating on this one point? Let us now say to the Minister, "If you are prepared to grant this privilege, then we are ready to discuss and do our best to adjust the other points in dispute and all join in on July 5."

Finally, Sir, I think Dr. Wm. A. MacIlraith's little letter (p. 565) contains an excellent suggestion that local doctors who feel they must enter the Service on July 5 should agree not to accept other doctors' patients who do not enter the service. This, I think, would be a very fine expression of

good faith between us. It would relieve and strengthen the timid and would weaken very little our stand against the Act as it is, at present.—I am, etc.,

Chiswell.

N. BEATTIE.

SIR,—It has been insisted that retention of the ownership of the goodwill of a practice is essential to the freedom of the doctor. No one has explained how this works out. "Ownership" of one's practice will not prevent any interference with liberty, such as the imposition of regulations as to (a) the use or non-use of drugs and methods of treatment, (b) certification, (c) limitation of lists (and so, indirectly, interference with free choice of doctor), and lastly (d) the requirement to complete a mass of unnecessary forms. The fact is that, once the principle of a State medical service has been admitted, as it has by the B.M.A., then the pass has been sold. No safeguards will prevent the abuses just mentioned.

If the principle of compensation is not admitted the cash value of a practice will certainly disappear. What young man will buy a practice with the probability or certainty that then or in the future it will be made easy to start in practice without the expenditure of any capital?

If these are not valid arguments, I would welcome reasons why they are not. If they are, what is the point of objecting to the abolition of the purchase and sale of goodwill?—I am, etc.,

Binfield, Berks

L. G. JACOB

Doctors Who Might

SIR,—I have not so far attempted to enter the present controversy. I do, however, resent the stigmatization as a fifth columnist by one Lieut.-Col. J. T. Harold (March 13, p. 518). It did not fall to my lot to have to leave a practice. It did seem to me to be rather a noble act for a man to leave a personal an undertaking as a practice, especially a single-handed one, as so many young and not-so-young doctors did during the war. I met many whose quarterly cheques dwindled to nothing as their practices continued to be "protected." I wonder whether Lieut.-Col. Harold experienced what these men felt. I believe that there are now about 5,000 ex-Service doctors with higher qualifications for whom there is little prospect of work outside the new Service, apart from a series of registrations. Perhaps Lieut.-Col. Harold would counsel these young men as to how they can face the problems of supporting a family and pay off life-assurance policies if they do not join the Service. At between 30 and 40 one cannot afford to accept £400-a-year appointments.

I have ten years' experience of a State service and I think it can work if a few points are observed. (a) Clinical freedom. This must include freedom from lay interference. Actually, it has been my experience that the standard of assistance in administrative affairs received from non-medical sources was often far superior to that to be expected from medical officers of "the administrative grade." The latter are often without more than minimal professional knowledge, but are able by its possession to sway potentially helpful lay authority. Lack of professional knowledge is balanced by the high rank often held. This will be confirmed by many ex-Service officers. I have often known the local (non-medical) commander care far more about the hospital than his medical counterpart. (b) Absence of intimidation of the professional cadre by the "office boys." The "punitive posting," familiar to us all, must not be available as a weapon to silence criticism. (c) The first loyalty must be to the patient. In this there will be no difficulty so far as I can see. I have sat on about 5,000 Boards and I have never seen a patient denied the benefit of the doubt. In these Boards, however, two of the three members were clinicians, and bureaucracy had no say.—I am, etc.,

Hoylake, Cheshire.

T. DENNESS

An Interim Plan

SIR,—The plebiscite has established clearly the determination of the medical profession to resist the National Health Service Act in its present form. The public utterances of Government spokesmen seem to indicate the Government's determination to impose it. The question which therefore becomes urgent is what action the general practitioner should take on the appointed day if fresh negotiations prove impracticable and we are obliged to refuse service.

The issue of the battle, if unhappily a battle is to be, would seem to depend upon our ability to find a substitute for the panel system to tide over the period between the termination of the present panel service and the settlement of the dispute. The characteristic feature of panel practice is the large attendance at surgeries. If we attempt to charge full private rates to these people, very many will stay at home or seek attention from one of the few practitioners who take service under the Act. In this way we might suffer a severe falling off of income and seriously antagonize the public. If, however, they are charged a very small fee they will probably continue to attend in considerable numbers. The practitioner will thus retain his connexion, the large turnover of small fees will provide him with an income which will at least partially compensate him for the loss of his panel cheque, and this will enable him to carry on without becoming a charge on the fighting fund.

A large notice in the waiting-room to the effect that the practitioner, while feeling obliged on principle to refuse service till the Act was amended, would attend his old panel patients at, say, half his normal private fees till the dispute was settled, might be very good propaganda. Finally, if when a patient presents a card or form for acceptance as a State patient his form or card were accepted, signed, and endorsed "subject to an equitable settlement of the dispute," or some such phrase, accompanied by a verbal promise that he should be taken on as a State patient when the matter was finally settled, it would have a better moral effect than simply turning the patient away with his form or card unsigned.—I am, etc.,

F. B. LAKE.

Committee of Those Who Accept

SIR.—The time has now arrived for the minority in the profession to consider its action. The B.M.A., I am pleased to see, are the first to state categorically that the N.H.S. Act allows complete freedom of choice as to entry into the new Service or not. I, like a few thousand others, although quite able to vote against the Act in its *present form*, do feel justified in accepting service under the Act.

Only three months remain in which to thrash out hundreds of minor details necessary to the smooth running of the Act. With the B.M.A. Council pledged by the S.R.M. not to negotiate with the Minister unless certain conditions are fulfilled, we are left with no one to discuss with the Minister these vital details, found by experience to be detrimental in the N.H.I. service, which could quite easily at the present time be corrected in the regulations for the new Act.

It would of course be quite impossible for members of the present Negotiating Committee to stand out against the Act on the one hand and to negotiate for the Act on the other. In view of this difficulty I would suggest that the B.M.A. form a separate committee of those practitioners who are going to accept service, together with three clerks to committees of the present N.H.I. service. With this body to represent those willing to take part in the Service, at least some order and intelligent planning of regulations would result.

If no such committee is formed then all the regulations will emanate from the Ministry of Health, which cannot have any practical experience in running insurance practices. The final Act, even with amendments in accordance with the B.M.A. policy, would still show a mass of poor regulations, which after the appointed day would be very difficult to change or modify.

As far as I am concerned—and I am sure that I speak for the vast majority of those that will take part in the Service—there need be no fear on the part of those doctors who stay out that any of their patients will be accepted on the State lists, at least for a full three months after July 5. After that date, as it is quite clear to everyone that a doctor can either enter the Service or not of his own free will, there will be no need for the N.H.S. doctors to consider from whom any patient applying for treatment may have come.

I would just like to add one word about the lot of the assistant. All those doctors not taking part in the Service will hardly be in a position to find the money to pay their assistants at the rate of £700 per annum. I suppose all these hard-working young men will find themselves out of a job on or about Aug. 1 of this year.—I am, etc.,

Old Church, Hants

EDWARD F. HUNT.

The Junior Partner

SIR,—July 5 will present me with a problem which I think must also face some other doctors in partnership. I should be interested to hear how they propose to solve this problem. I am junior partner to a doctor who is willing to come into the new scheme on the appointed day. I have expressed my willingness to abide by the majority decision. I am in considerable debt to my senior partner, as he has been very generous and helpful to me and I am still really only doing the work which before the partnership I did as his assistant—that is, I have so far by my admission to partnership done little to increase the size of the practice.

On July 5 all our present patients, private and insured, will sign on with my partner. What do I do? There seem to be two possible courses: (a) Dissolve the partnership and practice in an entirely new locality. This amounts to starting again, and with present commitments is a financial impossibility. (b) Revoke my decision and continue to work with my partner.

It is understood that there is no difference of opinion between myself and my partner, that I respect his decision, and that I have a moral obligation to continue to help him. Others may have a legal obligation to continue their partnerships until purchase is complete.—I am, etc.,

JUNIOR PARTNER.

Informing the Public

SIR.—Some Labour M.P.s are giving public lectures on the new National Health Service. They are emphasizing only the advantages of the scheme. They are also convincing the public that the doctors will join the scheme as they did in 1911. To achieve success it is essential that the whole profession pull their weight. I therefore suggest a few methods by which the rank and file of the profession can help.

(1) Every local B.M.A. Branch should arrange for a doctor to give public lectures on why the doctors disapprove of the new National Health Act. In these lectures stress must be laid on how the Act will adversely affect the patients. The following are examples of this: (a) The Service will be of a utility nature and not nearly the best that the profession can provide. (b) Criticism by those who understand (the doctors and nurses) how the scheme could be improved will die. Who can afford to criticize his master? (c) Direction of doctors must lead to direction of patients in their choice of doctor, specialist, and hospital. (d) Patients' medical records will be inspected by Government officials. (e) Patients will be forced in many cases to obey the doctor's recommendations—e.g., operations, etc.—in order to qualify for benefits. (f) Doctors will be forced to give certificates according to the orders of the Government. (g) The personal loyalty of the doctor will move from the patient to the State. (h) Medical appointments to practices and hospitals are bound to be influenced by the political outlook of the doctor rather than only by his professional ability. (i) The annual financial deficit of about £150 million in the cost of running the scheme. This must eventually entail new taxes or the weekly payment by patients must be vastly increased.

(2) In addition every doctor should be in possession of copies of a printed pamphlet entitled "Why the Doctors Disapprove of the New National Health Act." They should distribute these among their patients. Doctors like myself who have no civil patients would gladly distribute them at random among the population.

Finally, we must never forget that modern history has proved that unopposed propaganda can enslave a nation.—I am, etc.,

SERVICE PRACTITIONER.

Continuity of Practice

SIR.—The more the Health Service is argued the more one appreciates what a two-edged weapon is the phrase "comprehensive medical service available to all," and the greater grows one's apprehension lest all the principles put together prove insufficient to avert the bureaucratization of medicine, which has been and which should always remain the most free and individual of the sciences. Lord Horder's dictum that the Negotiating Body had cut concession to the bone is more likely to be an understatement than an overstatement. In these circumstances it is remarkable that some doctors should have apparently so little vision of the future as to believe that the

rescission of the basic salary will be sufficient in itself to maintain essential freedom. While this proviso may perhaps provide escape from the State salaried service in name and title it is very far from doing so in effect and in fact, as these innocents would very quickly find if the Government became the sole owner and patron of their practices—which Heaven forbid. It is by no means appreciated how great is the value to the public of continuity of practice. A doctor who buys a general practice purchases, as it were, a stake in the locality. Almost invariably he settles down for a term of years, and not infrequently for the whole of his working life. In the way that only time can give he gains a real knowledge of his patients, their characters, their interests, their antecedents, indeed almost everything about them. To him they are individuals, not numbers. Frequently and in a very real sense he is a father of his people. In due course he may be succeeded by his son.

Now consider what might well happen under Government patronage, the doctor being appointed to his living. There is no incentive to like the place or to care for the people, there is no incentive to remain, and indeed much inducement to keep moving. Thus he becomes no more than a temporary resident, or, more aptly, the equivalent of the political "carpet-bagger."

Those who are wavering or weak in the faith, and those who are casting anxious eyes at their compensation, should try to look into the future of ten, twenty, or thirty years hence, when their sons and successors will be practising, and should always remember that they themselves are but custodians, that the science of medicine is a heritage common to the past, the present, and the future. It is worth hazard or sacrifice, especially of personal position and amenity, if thereby that heritage can be passed on in all the greatness of freedom.—I am, etc.,

Wirksworth Derby

E. D. BROSTER.

Economy of Service

SIR.—If the available number of doctors is ever to deal with any contract covering the whole population great economy will have to be observed in the use of each doctor's time. It is not economic to use his time writing, dispensing, waiting for clinical laboratory services, x-ray services, and hospital beds. How reduce or eliminate these wastages? (1) Provide a shorthand typist for each doctor. (2) Provide a 24-hour 7-day dispensing service for the whole country. (3) Provide a "mobile" clinical laboratory service for the whole country. (4) Provide a "mobile" x-ray service for the whole country. (5) Provide a "mobile" consultant service for the whole country. (6) Provide at once sufficient hospital beds. (7) Establish a "one only incapacity certificate a week" service.

If (3), (4), and (5) are "mobilized" much work now absorbing hospital beds would be done at the patient's home, interesting cases would not be so entirely removed out of the care of their own doctor—to the advantage of both—so that this "mobilization" would have the effect at once of providing more hospital beds complete with staff. Such a development of the panel is a natural growth, and would work under the same sort of contract we have become accustomed to. The Spens Report covers the remuneration.

It would give the doctor the tools, leave him free, leave him subject to competition, and leave him responsible to his patient and his conscience.—I am, etc.,

Market Rasen, Lincs

DUDLEY F. TORRENS.

Benefits for Doctors' Wives

SIR.—I should like the opportunity of replying to the letter from Mrs. Gladys M. Woolf (March 13, p. 520). She is indeed more fortunate than most doctors' wives in that she has had a maid throughout the war. We have received many hundreds of letters from doctors' wives enclosing their subscriptions to the League of Doctors' Wives, and the gist of most of them is that the only time they are able to leave their homes to do any shopping is whilst their husbands are working in the surgery, because they have had no domestic help.

The doctors' wives are quite distraught at the thought of what is to happen on July 5 when the number of patients actually attending the doctors' houses will probably be trebled.

In addition to this there will be all the extra paper work which will have to be seen to by the doctor or his wife. There will be record-cards for every patient on which every item of service—even if it is only a repeat medicine or a certificate—will have to be entered. The doctors' wives feel that this burden is too great for either their husbands or themselves after the long exhausting years of the war. There is little opportunity for these women to leave their homes with their husbands on social visits in the car as Mrs. Woolf suggests, because the house cannot be left unattended. We insist that the Minister should have made some provision in his Act for the essential domestic and secretarial help which this scheme will necessitate.—I am, etc.,

IRENE HARTLEY,

Camberley, Surrey

President, League of Doctors' Wives

SIR.—It is with some regret that I write to dispel a little of the sunny light of favouritism in which Mrs. Gladys M. Woolf (March 13, p. 520) imagines that she, as a doctor's wife, is basking.

(a) The practice of medicine being considered an essential occupation during the war period, maids of military age were allowed to remain in the employ of doctors because their services were considered necessary for the efficient carrying on of those practices and not out of compliment to the doctors' wives.

(b) Income-tax allowances are granted to all professional or business men whose professional or business activities involve them in unavoidable overhead expenses. Since this perfectly fair concession is made to any person entitled to claim it, precisely why it should now be regarded as designed for the particular benefit of the doctor's wife entirely escapes me.

(c) Doctors have been permitted to use their cars for recreational purposes, as they occupy the surely unique position of always being liable to recall, thus giving the frailest possible guarantee of their being able to enjoy any leisure time and certainly not with that feeling of absolute freedom with which other sections of the community are blessed.

What a pity it is that Mrs. Woolf is unable to secure for us in the heart of the Minister of Health the "soft spot" which she appears to think exists in those of the Ministers of Labour, Fuel and Power, and the Commissioner for Inland Revenue. All our troubles would then indeed be over.—I am, etc.,

Hayas End, Middlesex.

MARGARET ELMES.

Relief of Pain in Midwifery

SIR.—Dr. C. A. Allan (Jan. 24, p. 175) states that it is surprising that so little attention is given to the problem of analgesia in labour. The true position is that the perfect analgesic for labour has yet to be discovered and that the objections to many of the available analgesic agents are so great that many doctors avoid their use not from callous indifference but from a distrust and appreciation of the dangers of such methods as prolonged narcosis with the barbiturates or the opium alkaloids, and from the experience that the use of Minnitt's apparatus and other methods of gas-air analgesia have been unsatisfactory.

In my experience the objections to the barbiturates have been principally in their effect upon the foetus. If an adequate relief of pain is obtained for the mother the foetus is frequently slow to respond at birth, and I am sure that every now and again a foetal death results from the use of the barbiturates alone.

The uses of morphine-hyoscine narcosis and similar methods may give rise in a considerable proportion of women to uncontrollable excitement which may cause extreme difficulty in delivery, and particularly in the management of a patient in her home.

Minnitt's apparatus, in an investigation in which I took part in 1934, gave satisfactory analgesia in 94% of cases, the criterion of satisfaction being the joint opinion of the obstetrician-in-charge and the patient. There is no doubt that when used by a patient who has been familiarized with its use, as advocated by Dr. Anne M. Toms (March 6, p. 475), it is a very valuable method indeed, but in various parts of the country I have found a regrettable ignorance of the proper use of the apparatus on the part not only of the patient but, as Dr. Allan points out, of the doctor or nurse. The substitution of pure nitrous oxide inhalation for the gas and air of the Minnitt apparatus, as advocated by Dr. H. Thistlethwaite (Feb. 14, p. 318) and Dr. R. John Gourlay (Feb. 23, p. 417), carries with it a danger of foetal anoxia, as in the case quoted by the latter writer. In many cases a very short period of anoxia may

be sufficient to determine a fatal outcome for a foetus, possibly already suffering from the strain of prolonged and difficult labour, and for this reason it seems to me that the safety factor of the air inlets in the Minnitt apparatus is of prime importance.

In the United States and to a less extent in this country the recent interest in continuous caudal and saddle-block spinal anaesthesia, and in other local anaesthetic methods, has been followed by enthusiastic reports from various authors, and one of the most recent of these (Hingson *et al.*, *J. Amer. med. Ass.*, 1948, 136, 221) claims to have demonstrated a considerably lower mortality rate where these methods have been used than in cases treated by systemic narcosis or general anaesthetics. They point out that the stillbirths and neonatal deaths were four times as great in cases where no anaesthetic was used as in those where local and regional anaesthetics were applied. This is probably an even more cogent argument for the use of analgesics than the dictates of common humanity, but it is impracticable to undertake these particular methods in any but large, well-equipped, and fully staffed hospital units owing to the prolonged and continuous supervision required.

The use of pethidine described by Miss Josephine Barnes (April 5, 1947, p. 437) gave relief in 87% of patients: It is a method simple to apply and safe for both mother and foetus, and in my experience leads in a considerable proportion of patients to strikingly easy labour. 100 mg. of pethidine should be given as soon as pains are well established, and repeated in three hours if necessary and if delivery does not appear imminent. This gives ample analgesia in the majority of cases, but in a few women it appears to be inadequate and in these the addition of morphine gr. 1/4 (16 mg.) by hypodermic injection will usually prove satisfactory.

One is forced to the conclusion that, as has been so often stressed before, the ideal analgesic method for labour has yet to be discovered, but in general practice the use of pethidine or morphine, with an inhalation anaesthetic for delivery such as "trilene," or even the much maligned chloroform in small dosage, is still probably the most satisfactory practicable method—I am, etc.,

Inverness.

J. A. CHALMERS.

Leucocytosis following Treatment with Thiouracil

SIR.—The toxicity of thiouracil has been much discussed in the past few years in English and American literature. There were some cases with agranulocytosis, but leucopenia was described as the usual reaction. In the case reported below—treated with methylthiouracil—a significant leucocytosis was observed with marked increase of lymphocytes.

Female, aged 37. Diagnosis—Graves-Basedow disease, cardiomyopathy compens. Basal metabolism rate +32%. White blood cell count 8,000.

The treatment was started with minimal dose. The total dose of 4 gr. (0.25 g.) was reached only on the 13th day. On that day the white cells—previously constant at 8,000 per c.mm. even on the 10th day of the treatment—were 15,000 in number. 1.25 gr. (81 mg.) was added during the following two days. The white cell count was still high, 16,500. Then treatment was stopped. Two days later the white cell count was 9,000 and this remained unchanged the following 6 days.

The differential count at the leucocytic state: neutrophil metamyelocytes, 2%; band forms, 4%; polymorphs, 36% (5,600 in absolute count); eosinophils, 12% (1,850); lymphocytes, 40.5% (6,200); polymorphocytes, 4%; Gumprecht's shadows, 1%; monocytes, 0.5%. Two days after treatment was stopped; neutrophil metamyelocytes, 0%; band forms, 2%; polymorphs, 59%; eosinophils, 7%; lymphocytes, 30%; monocytes, 2%. Five days after this: neutrophil metamyelocytes, 1%; band forms, 4%; polymorphs, 57%; eosinophils, 4%; lymphocytes, 32%; monocytes, 2%.

The bone marrow at the time of the above deviation was unchanged. Lymphoid cells were not increased. Subfebrility, tachycardia, and basal metabolism rate remained unchanged. The response to treatment was nil.

Szeged, Hungary.

E. KELEMEN.

Trichlorethylene in General Anaesthesia

SIR.—As Dr. Ronald Millar (March 13, p. 524) has rightly pointed out, the use of trichlorethylene in anaesthesia is still in its trial stage, and it behoves anaesthetists to report their experiences with the drug so that the full range of its useful and harmful properties may become known.

Dr. Millar reports several interesting observations regarding trichlorethylene which concur with my own experiences of the anaesthetic. I cannot agree with him, however, that a per-

centage of oxygen as low as 20 should be used with trichlorethylene. Owing to the diminished depth of respiration, I have found that CO₂ "build-up" and anoxia will occur unless a good flow of gases (at least 6 litres a minute) and 30% to 40% oxygen are given, especially in longer cases. I cannot help feeling that the increased muscular tone observed by Dr. Millar is at least partly due to hypoxia.

Dr. Millar's case of jerky abdominal movement under trichlorethylene is very interesting, as I had a similar case not long ago. The condition commenced during a period of strong surgical stimulation; a change over to ether did not completely abolish the abnormality, but within a matter of ten minutes the condition improved, and by the end of the operation respiration was normal.

I have had one case of "false anaesthesia" resembling that described under chloroform.¹ The patient, a healthy woman of 39 years, was to undergo Keller's operation. Six ml. of 5% thiopentone was given, followed by gas-oxygen-trilene with a well-fitting mask. A tourniquet was applied, and ten minutes later, when the surgeon was ready to start, respirations were regular, the limbs were relaxed, and the eyelash and eyelid reflexes were absent. The surgeon's knife showed that the patient was not indeed anaesthetized, but fortunately the deepened respirations ensuing rapidly brought on true anaesthesia.

Unlike Dr. G. Ostlere (Jan. 31, p. 195) I have had no complaints that trichlorethylene increases bleeding. On the contrary one or two surgeons have expressly asked for it because of the diminished capillary oozing. This accords with Dr. Langton Hower's view.²

Finally I should like to say that I have found trichlorethylene very useful for ensuring a smooth transition from gas-oxygen to ether (preparing the larynx, as it were, for the stronger stimulus to come), and for most cases where anaesthesia deeper than stage 3, plane 1, is not required—provided always that adequate oxygen is given, that the warning signs of tachypnoea and cardiac arrhythmia are acted upon, and that the minimum only of the drug is used.—I am, etc.,

MARK SVERDLOW.

SIR.—I should like to express my appreciation of the criticism afforded my paper on trichlorethylene. There are three points in this recent correspondence upon which I beg leave to comment.

1. Safety. No fatality definitely incriminating trichlorethylene was described by any correspondent.

2. Oxygenation. We have found that in appropriate cases a mixture of 20% oxygen and 80% nitrous oxide is suitable for maintenance. Small amounts of trichlorethylene may be added to this mixture as necessary. It was finally considered that increasing the oxygen percentage when trichlorethylene was employed, which was the usual practice at Hill End Hospital between 1940 and 1944, did not decrease the tendency of the drug to produce tachypnoea. I must apologize for not making clear that adequate oxygenation of the patient is essential as with the employment of any anaesthetic agent, and that we administer up to 50% oxygen with trichlorethylene if the tidal air is markedly decreased by the action of curare. If the tidal air remains at or above normal volume an increase of the inhaled oxygen from 20 to 100% only slightly raises the oxygen content of the arterial blood.

3. Intubation. We perform nearly all our nasal intubations under trichlorethylene, a few breaths of which, following induction with thiopentone, have always appeared to establish sufficiently deep anaesthesia to prevent the appearance of vagal reflexes. Breath-holding and coughing may occur, although the patients rapidly settle down. The danger of the respiratory disturbances following intubation in light anaesthesia has been noted by Gillespie (*Endotracheal Anaesthesia*, 1948, p. 145, Wisconsin): "If the function of the patient's heart or lungs is seriously handicapped by disease, even a slight lack of oxygen, such as can be caused by holding the breath, may be sufficient to cause death." This may be the explanation of some deaths attributed to "reflex factors" and emphasizes the care that should be taken for the full oxygenation of such cases, but hardly condemns trichlorethylene out of hand as an unsuitable agent for intubation. However, I do not wish to become involved in a discussion of intubation in light anaesthesia.—I am, etc.,

Hill End, St. Albans.

GORDON OSTLER.

Natural Position in Childbirth

SIR,—I was much interested in Dr. Kathleen Vaughan's letter (Jan. 31, p. 222). I have seen women in Persia deliver themselves in the squatting position, walking to the doorway of their hut to do so. Placenta followed baby almost immediately, and there were never any perineal tears. The babies, however, were always small, averaging 5½ lb. (2.5 kg.), and with much smaller heads than most English ones.

In practice I have found the best position for the woman is on her back, with plenty of pillows under her shoulders, and the knees well-flexed—in fact the nearest thing to squatting. The women tell me they can use their pains much better than in the lateral position, and indeed it seems natural that it should be so. If one happens to be single-handed it is easier to control the patient, and for doctor and mother to co-operate. I believe this is the French practice.

As regards perineal tears and stretching of the perineum (which can result in much more lasting damage than a simple tear), I am inclined to think that episiotomy is the answer.

I would like to add that I am the mother of four children, my eldest being born when I was 32. I was never delivered in the "natural" position, but I practised squatting frequently during the last month of pregnancy and during labour. My babies were always born quickly and easily.—I am, etc.,

Kendal, Westmorland.

FRANCES M. TAYLOR.

Health of Students

SIR,—May I comment on some of Dr. John Pemberton's conclusions (March 13, p. 490)? He states that "some 20% (of students) were found to be suffering from minor anxiety states and depression." He gives as an example of this that they were afraid of failing their examinations, with all that that entails nowadays. Surely, Sir, this is a normal and very temporary state to be in, or does Dr. Pemberton consider it abnormal to be afraid of ploughing an examination? His other example of anxiety state is that 9% had insomnia (whether permanent or just before examinations is not stated). He uses as a standard an inability to fall asleep after being in bed for one hour. Is this really meant as a scientific standard? I suggest that Dr. Pemberton talks to a junior probationer nurse, who will tell him about patients who "never sleep a wink" yet manage to snore all night.

In the section on orthopaedic defects he claims an incidence of 34%, with 14% having flat foot. I wonder if Dr. Pemberton realizes that there is a difference between a flat foot and a foot which looks flat but which stands up to playing tennis, Saturday night dances at the Union, Sunday hikes, and other strenuous activities. Those of us with considerable experience of having cases referred to us after routine inspections of school-children and Service men know that this is a common error.

There is claimed to be a 16% incidence of postural defects of the spine, that is "scoliosis, kyphosis, and lordosis" (*sic*). Even if I were prepared to believe that such a high incidence of abnormalities was present, I must disagree with his conclusions. He states, "Most of the orthopaedic abnormalities found were due to lack of muscle tone and physical development, and could perhaps have been prevented by better previous physical education. They emphasize again the value of adequate and easily available facilities for athletics, sports, and gymnastics as a positive contribution to student health." Later he further states, "The frequency of postural and other orthopaedic defects raises the question of the value of compulsory physical education such as has been introduced for freshmen in at least one British university." Has Dr. Pemberton the slightest evidence to support these conclusions? Does he think that gymnasts never suffer from flat foot or postural scoliosis? Has he any proof that exercises have ever prevented or cured these conditions? I am, of course, quite aware that this is a very common but nevertheless erroneous belief, and that in your leading article you state, "Yet even a young person with severe kyphosis and unfit for most sports may overcome his handicap by learning to swim on his back." If a kyphosis is amenable to treatment it is by developing secondary curves above and below the lesion, and surely a breast and not a back stroke would best do this.

Social medicine has been claimed as "a new scientific approach to medicine." Where are Dr. Pemberton's controls? Has he examined a similar group of non-students to find out how many of them had postural defects or had ever lain awake

at night? Did he discover the relative incidence of postural defects in those students who do and those who do not play games? Is there a significant difference between those who had compulsory physical exercises and games at school and those who did not?

Many medical men have wondered what the exact function of social medicine is. I hope it is not to produce field surveys without any controls.—I am, etc.,

Sheffield.

SIDNEY PAPPWORTH.

Intervertebral Disk Lesions

SIR,—Dr. J. Donaldson Craig and Mr. A. W. Lipmann-Kessel's letter (March 20, p. 570) on this subject is most illuminating. Andrew Taylor Still and, subsequently, the osteopaths have for sixty years suggested that sciatica and many other referred neuralgic pains are "due to joint disturbances." Evidence is gradually accumulating to prove there is more truth and value in the osteopathic theory than has so far been admitted by the orthodox medical profession.

While from the patient's point of view it is probably unimportant where and by whom knowledge is developed, it is only fair, in my opinion, that medical writers should give credit to the author of any theory they propound or elaborate.—I am, etc.,

London, W 1

GEORGE MACDONALD.

Diagnosis of Relapsing Fever

SIR,—With reference to the interesting paper of Drs. R. I. Bodman and I. S. Stewart (Feb. 14, p. 291) the following notes on diagnostic difficulties in sporadic cases of relapsing fever might be of some interest.

Sporadic cases of comparatively rare diseases often present diagnostic difficulties. Four cases of relapsing fever were observed here in the period from May, 1946, to November, 1947. Three ran a typical course, and *Spirochaeta recurrentis* could easily be found in the blood smears of two, whilst all responded well to nearsphenamine. The fourth case caused considerable anxiety and was first considered an acute abdominal condition, then typhoid, until his temperature chart and prompt response to a single injection of 0.45 g. of nearsphenamine disclosed the true nature of his grave condition.

The case history was as follows. A farmer aged 40 was taken ill with high temperature on May 5, 1946. Next day he was admitted to a surgical ward with colicky pain in the right hypogastric region. W.B.C., 15,000; B.S.R., 20–40 mm. He was given sulphadiazine orally (28 g.) and his temperature returned to normal. On May 13, seven days after his admission, he was discharged at his own request, only to be readmitted on May 25. Once more his temperature was around 38° C. (100.4° F.), which did not subside after another course of sulphadiazine (30 g.) and 180,000 units of sodium penicillin. His spleen was enlarged, and he was transferred to the fever department. The Widal was negative, and, as his temperature chart took on a recurrent character with attacks of fever alternating with temperature-free intervals, relapsing fever was suspected. By now, nearly 5 weeks from his first attack, his general condition had become very critical, and without microscopical confirmation 0.45 g. nearsphenamine was injected. He responded promptly, and his temperature dropped to normal within 24 hours, after which his general condition improved steadily. He was in perfect health when last seen in September, 1947, more than a year after his illness.

—I am, etc.,

Kosice, Czechoslovakia.

I. FRIEDMANN.

Appendicular Dysfunction

SIR,—Chronic appendicitis or appendicular dysfunction is a difficult condition to diagnose with any degree of certainty. The physical signs are minimal or even absent, excepting perhaps during an exacerbation.

The surgeon has therefore to make a diagnosis from the history and exclusion by investigation of other types of right-sided pain. It was with interest, therefore, that I elicited a physical sign during the examination of a case of abdominal pain and indigestion which pointed quite definitely to the appendix being the cause of a patient's symptoms. The patient,

had been referred to me with a diagnosis of a duodenal ulcer, and on pressure over the appendix the pain was referred to the umbilical region and reproduced the pain of which he was complaining. This clinical finding could be repeated at will.

The mechanism of the sign was apparent at operation, as the appendix contained a large faecolith, distal to which there was a collection of mucus. Pressure on the appendix therefore probably increased intra-appendicular pressure and produced the referred pain already described. It would seem most unlikely that this observation has not already been described in the voluminous literature regarding appendicular dysfunction. It is, however, not described in Hamilton Bailey's *Demonstration of Physical Signs in Clinical Surgery*, which is a very comprehensive treatise on this subject.

McBurney's sign is used extensively in the diagnosis of appendicular dysfunction, but the sign described above requires more generalized pressure in the right iliac fossa, and it should be possible to obtain it in any case where the appendix contains fluid in its lumen associated with partial obstruction and complete obstruction. This is a dangerous type of appendicular dysfunction, as perforation and peritonitis are likely to occur should acute infection supervene.—I am, etc.,

Newcastle-upon-Tyne.

F. DENIS HINDMARSH.

The Lazy Eye

SIR,—During the four months that have elapsed since my letter to you concerning defective vision in recruits (Nov. 15, 1947, p. 796) some forty to fifty boys have been referred every fortnight to the ophthalmic centre which I attend because their vision in one eye is 6/12 or less. In the intervals of refracting them I have read with keen interest the letters that have appeared in your correspondence columns on the school ophthalmic service and the lazy eye.

As a Devonian I was pleased to learn from Dr. Margaret L. Foxwell's letter (Jan. 31, p. 228) that the Devon County Council made all their school-children read the letters on the chart. I was equally delighted to read in Dr. Francis J. Lorrimer's letter (March 6, p. 476) that Kent County Council had "a plan." I sensed Mr. S. Black's frustration (Jan. 10, p. 77) at the non-fulfilment of the various recommendations of the committees. I was appropriately horrified at Dr. Mark Bradford's statement (March 6, p. 476) that the health visitor had to do the "eye testing" because the doctor was driven too hard by time and bureaucracy's relentless pressure. I shuddered at the thought of the school medical officers having to do a yearly refraction of every school-child at Mr. Black's behest (Feb. 21, p. 368).

I wondered about the type of "refractive error" which afflicted 70% of Dr. John Pemberton's Sheffield students and which only required 37% of them to wear glasses. But I became really angry when I read that one-third of the 150 students had either the wrong spectacles or else none at all (March 13, p. 490). So I went and dug out some figures on the eye defects of recruits. Apparently when they were trying to estimate the number of men who would be wearing spectacles if such were to be permitted on active service in the Boer War, the answer was 5%. During the 1914-18 war some 4% of the men in the average division were said to need glasses. The Americans rejected 8% of their "Draft" for visual defect, and calculated that 4% needed to wear spectacles. In the recent war the Americans estimated that 6% of their enlisted men had vision in the one eye of 6/18 and below. Some sample analyses of National Service recruits in the United Kingdom during the winter 1946-7 showed that 8% had vision of 6/18 in the one eye and below. Approximately 5% of the whole entry needed spectacles.

Therefore it would seem that though a considerable amount of hard work and good will has gone into the treatment of the ophthalmic conditions of the school-child, the end-results cannot in any way be held to be satisfactory. The hard core of the problem remains for solution—that 10% of the children need a thorough examination by an ophthalmologist, and that 5% will need to wear spectacles.

I trust, Sir, that you will regard this letter as fair comment. Admittedly I do not advance any constructive policy; I hope, however, that the scheme that is receiving consideration by the Council of the Faculty of Ophthalmologists will provide a successful solution.—I am, etc.,

London S.W.1

G. C. DANSEY-BROWNING.

The Department of Medical Photography

SIR,—In his unusual article entitled "Where are we going?" Dr. Ff. Roberts (March 13, p. 485) devotes half a column to clinical, or better termed medical, photographic departments. His comments in this connexion rest beneath the curious subtitle "The Fetish of Perpetual Expansion," and it seems unfortunate that of the many examples which could be marshalled to illustrate this section Dr. Roberts has chosen one which lends but little support to many of his arguments.

As one of the authors quoted without context, I would submit that subsequent remarks concerning Pasteur, Thomson, and Hopkins are both facetious and irrelevant. The very extent of quotation in this complete reference seems indicative of a lack of first-hand experience and hence detracts from any conviction apparent in other passages.

By the very nature of their work medical photographic departments are further divorced from the general run of hospital practice than are many of the other special departments: in many instances they are to be found in the medical schools and not in hospitals. It seems only fair to point out that these departments do not exist primarily to ease the burden of the clinician, to conserve manpower, or to show an economic return in the strict sense of the term: the accent is, or should be, placed far more on the record and educational aspects.

As the above comments are not offered in any sense of justification for the existence of medical photographic departments, no further elaboration should be necessary. It would be interesting to know, however, if Dr. Roberts would condescend to use lantern slides and material for publications prepared to meet his own requirements, or if he would prefer to perpetuate cracked and faded slides, and further blur the impression of half-tone blocks monotonously copied from book to book?—I am, etc.,

London, S.W.1.

PETER HANSELL.

Alcoholics Anonymous

SIR,—You have no doubt heard before this of our organization, which, though American in origin, has in the past year commenced activities in Great Britain. We have already had some measure of success and are now enrolling new members every week.

A brief description of our aims and objects appeared in the *Lancet* last year, and from time to time the daily, Sunday, and weekly Press have had articles about us. We are most anxious, however, to have the approval of the medical profession as a whole, as we consider that without any doubt the best approach to an alcoholic patient is through his or her own doctor.

In recent weeks we have had contacts with many doctors, and not only have we had no adverse word of criticism from them, but several have written to us or telephoned to us in terms of the warmest commendation. In particular they appreciate our help in rehabilitation of the patient after medical treatment. Needless to say we have no patent medicine, nor do we offer any form of medical treatment, though it often falls to our lot on meeting a new patient who asks for our help to recommend that he obtains treatment from his or her own doctor. We claim that our most valuable work lies in showing to the alcoholic who wishes to recover, through our own personal example, that it really is possible to achieve total abstinence and at the same time find an entirely new and completely happy way of living.

Above all we like it to be very plainly understood that we are not a reform society, and we have no interest in alcoholic patients unless they have a genuine desire to stop drinking. We expect them to approach us, or at any rate to express to someone else a desire to hear more of our methods.

I should be most grateful if you would allow me space for this letter, and in particular if you would state that we would welcome enquiries to our monomark address, simply "BM/AAL, London, W.C.1." For your own information, I enclose my name and address as a guarantee of good faith, and regret that our rules compel me to sign this letter,

ALCOHOLICS ANONYMOUS.

POINTS FROM LETTERS

Make Act a Success

Dr. G. POLLOCK (London, S.W.13) writes: After plodding through the letters (March 6) on the National Health Service I came to the name Aleck Bourne (p. 465) before I had read his letter. With most of the letters that I had just been reading in my mind, I had a feeling that I was going to be disappointed by seeing such a writer marching forwards (or is it backwards?), the victim of the psychology of the crowd. My mind, however, was soon set at rest when I found him calling attention to the doubtful value of the answers to Question A, and I agree "that scarcely a single doctor—perhaps not even Mr. Bevan himself—could have answered 'Yes' without mental reservations." Confusion of the issue could not have been more successfully brought about by the phrase in its present form, even if someone had set out with the deliberate purpose of causing confusion by a choice of words. . . . Mr. Aleck Bourne says that this is not a time "for battle-cries and the metaphors of war." The words of Lord Palmerston as quoted in *States and Morals* by Prof. D. Weldon aptly apply: "Half the wrong conclusions at which mankind arrive are reached by the abuse of metaphors, and by mistaking general resemblance or imaginary similarity for real identity." Not only the metaphors of war have been used, for I see the use has been extended into the ethical or moral sphere. I don't think it was quite the meaning intended in the New Testament language, "what shall it profit a man if he gain the whole world and lose his own soul," that it can rightly be applied as a censure to a doctor who expresses his intention to help to work the National Health Insurance scheme. I remember well the controversy and emotional upsets of the time of the introduction of the panel system, and I am resolved to do my best to make this Act a success. I believe that the doctors of the future will be quite able to secure any necessary improvements in their conditions as the need for these becomes apparent.

Only a Beginning

Major J. STARTIN, R.A.M.C.(ret.), writes: With reference to the leading article "Only a Beginning" (March 6, p. 454), I think the profession should ask themselves the questions (1) Is this the beginning of further opposition to the Act? or (2) Is it a suggestion that a more open view should be taken, as regards the Act as a whole, with the health of the nation at stake? I hope the answer to (1) is No and the answer to (2) is Yes. . . . During 20 years' service in the Army I never had any interference with my clinical work. We worked as a team with the team spirit. We had a large proportion of highly qualified men as specialists, and I think we may say that such men as Sir Ronald Ross, Sir William Leishman, and Sir Leonard Rogers made no small contribution to the advancement of medicine and the health of the universe. These men were bred in the Government service of medicine, in which I was proud to serve. I appeal to you gentlemen, in the words of John Hunter, "Don't think, try it!" Is the profession to remain *in statu quo* or is it to strive after higher ideals?

Good Policy

Dr. H. T. N. MERRICK (London, S.W.5) writes: In *Ulster Commentary*, February, 1948, published by the North of Ireland Government, the North of Ireland Minister of Health in a recent speech said: "The health scheme is being left in the hands of those who are accustomed to the work. The Government's part is to provide the means to enable them to get on with their job." This is a good policy for the B.M.A.

Simple Certificates

Dr. P. S. D. GOWERS (Sheffield) writes: However the National Health Service is organized, may we ask for simplicity in certification forms? I would suggest that the name and address spaces on prescriptions and all certificates in common use be identical in size and spacing, facilitating the use of carbon copies.

Severe Reaction to Penicillin

Surgeon Commander J. C. GENT (Dartmouth) writes: With reference to correspondence on the subject of severe reaction to penicillin the following case may be of interest. On Feb. 20 an officer aged 35 reported complaining of a sore throat and swelling in his neck. His temperature was 101° F. (38.3° C.). There was tonsillitis with an acutely inflamed left tonsil which had become ulcerated at its upper pole. The glands in the angle of the jaw on the left side were enlarged and tender; the skin over them was red and tense. He was given gargles, local kaolin poultices to the neck, and sulphathiazole internally. His condition improved rapidly, but he continued to run an evening temperature up to about 100° F. (37.8° C.), and on Feb. 25 penicillin therapy was started. 30,000 units of the sodium salt were given intramuscularly at 1 p.m. At 3.30 p.m. he had a rigor, and another 30,000 units of penicillin were given at 5 p.m. Soon after this he noticed a rash beginning to appear on the flexor surfaces of his forearms.

When I saw him at 6 p.m. his temperature was 102° F. (38.9° C.) and there was a morbilliform rash involving the flexor surfaces of his forearms and his trunk, front and back. The rash had avoided the face, and there were no Koplik spots. He complained that his throat was more painful, and the glandular swelling in his neck had increased in size. No more penicillin was given. He slept well; his morning temperature was normal and the rash had completely disappeared. Thereafter his recovery was uneventful and he remained afebrile save for a slight evening rise of temperature to 99° F. (37.2° C.) on Feb. 27. He was discharged to his ship on March 1.

To my mind the point of interest is that the rash was morbilliform in character, as I have not previously seen any mention of this type of rash following penicillin. It is arguable, of course, that it was in reality due to the sulphathiazole, but I think this is unlikely as he had had 21 g. without any signs of intolerance and the rash disappeared as soon as the penicillin was stopped, though sulphathiazole was continued. Moreover there were the constitutional symptoms—rigor, etc.—which made their appearance within an hour-and-a-half of the first injection. Another point is that his temperature, which had been rising to 100° F. or thereabouts at night before penicillin, settled afterwards in spite of the severe reaction. Could the rash in reality have been a toxic manifestation due to the sudden release of toxins resulting from the destruction of a large number of organisms? I should be interested to know if any similar cases have been experienced.

Dr. KENNETH MACKENSON (Isle of Tiree, Argyll) writes: I was much interested in the cases of severe reaction to penicillin reported by Dr. D. Heffernan (Feb. 7, p. 277), Dr. J. F. L. Wallis (Jan. 24, p. 150), and Dr. William Corner (Feb. 28, p. 417), and so perhaps my own personal experience of a severe reaction after treatment by penicillin for two-sided acute lobar pneumonia on two occasions within the last twelve months may be of some interest to others.

In the years 1946-7 I suffered from three attacks of two-sided lobar pneumonia within the space of eighteen months and at intervals of six months. The first attack was treated successfully with sulphapyridine, and there was no reaction of any kind.

The second attack failed to respond to sulphonamide treatment, and 3-hourly injections of penicillin were resorted to. After five days of 3-hourly injections of penicillin the temperature dropped and the injections were stopped, but unfortunately there was a relapse and the 3-hourly injections of penicillin had to be continued for a further period of five days, when the temperature again dropped and the chest condition gradually cleared up. On getting out of bed and attempting to dress I had great difficulty in getting my coat on, on account of pain and stiffness in the left shoulder-joint, and all movements of the joint became difficult and were greatly restricted. The pain and stiffness increased and I was compelled to go to hospital to have the shoulder-joint manipulated under an anaesthetic, and this was followed by physiotherapy for three weeks.

The left elbow-joint was also painful and stiff, but not too troublesome, and I had recovered the use of my left arm to a large extent. When I developed the third attack of two-sided lobar pneumonia, which was also treated with fairly large doses of penicillin by injection, and very successfully treated. No sooner had the chest condition cleared up than there was a return of the joint pains and stiffness—this time in the right shoulder-joint and also in the left elbow-joint. After three weeks of massage and radiant heat treatment the shoulder-joint gradually improved, but the left elbow-joint still gives a lot of trouble at times.

At the time I was of the opinion that the pain and stiffness of the joints was a reaction to the penicillin, and now after reading the letters I have already mentioned I am more convinced than ever that this is the case. There was no reaction whatsoever after the attack which was treated with sulphapyridine.

Relief of Pain in Midwifery

Dr. MARTIN JENNER (Woking, Surrey) writes: I cannot agree with Dr. Anne Toms (March 6, p. 475) when she says that the pains of perineal stretching in labour "in most cases call for anaesthesia." Having worked in close association with Dr. Dick Read for some time I have seen many cases conducted both by doctors and midwives according to his ideas. Of those women interested and instructed in their task of childbirth it is unusual to meet one who will use the "trilene" inhaler or Minnitt's machine during the second stage of labour, although these are freely offered to all of them.

At the start of perineal stretching most women are a little apprehensive, but near "crowning" the perineum is insensitive, and should it rupture the actual tearing is never felt. The delivery of a case instructed in this way gives the mother more joy than pain, while the purely obstetrical advantages of delivery with the full co-operation of the mother and trouble-free third stage have to be seen to be believed. . . .

Obituary

W. R. REYNELL, M.A., D.M., F.R.C.P.

We announce with regret the death on March 21, at the age of 63, of Dr. Walter Rupert Reynell, who until two years ago was senior physician to the West End Hospital for Nervous Diseases.

Dr. Reynell was born in South Australia and educated at Queen's School and St. Peter's College, Adelaide. In 1906 he came to Balliol College, Oxford, as a Rhodes scholar, and there he distinguished himself as a boxer and at tennis. He was a student at Guy's Hospital and graduated in 1913, a year after he had taken the conjoint diploma. He was a house-surgeon, out-patients officer, and house-physician at Guy's Hospital until July, 1914. He served with the R.A.M.C. in the 1914-18 war and was with the Australian Voluntary Hospital in Belgium for some time and at the Seale-Hayne Hospital for neurological cases at Newton Abbot.

Dr. Reynell took the M.R.C.P. in 1918, and was elected assistant physician to the West End Hospital for Nervous Diseases in 1920 and physician in 1926. Most of his active work was done at this hospital, and he soon became more interested in the psychopathological problems of diseases and disorders of the nervous system than in the purely organic side of neurology. He was always a sound neurological diagnostician, but he devoted an increasing amount of his time and energy to psychotherapy. His interest in this work was well shown in some of the papers he published in the 1930's on morbid depression and anxiety and similar subjects. In 1934 he was elected F.R.C.P. Then early in 1940 he was again commissioned in the R.A.M.C., and with the rank of major he joined the Hospital for Head Injuries at Oxford. There he continued to work throughout the war, concerning himself mainly with the psychiatric aspects of head injuries. He returned to London at the end of the war, but retired from the West End Hospital in 1946.

Dr. C. Worster-Drought writes: W. R. Reynell was my valued hospital colleague for more than twenty-five years; very early in this period I became aware of his reliability, loyalty, and integrity, the realization of which increased as the years passed by. Always of somewhat retiring disposition, at times almost self-effacing, he disliked teaching in the form of set lectures or demonstrations and was not altogether keen on hospital committee work. Nevertheless he could always be relied on to respond to any suggestion that his help in a course of demonstrations would be appreciated, or that his presence at a particular committee would be of value. In such circumstances the opinions he expressed were invariably sound and of great assistance. On many occasions of difficulty with regard to hospital matters I have been deeply conscious of his loyal co-operation. One could always discuss any such problem with Reynell and be sure of sympathetic understanding and sound advice.

In earlier days he was attracted by the more organic aspects of neurology, but gradually became more and more interested in the psychopathological problems of nervous disease, and particularly in psychosomatic disorders. In the out-patient department Reynell was at his best, and there is no doubt that he was happier in the purely clinical side of his work than in any other. Reynell, a great sportsman, will be sadly missed by patients and colleagues alike.

Dr. W. Ritchie Russell writes: Throughout the late war Dr. Reynell was a much valued member of the staff of the Military Hospital for Head Injuries, Oxford. His wide experience of practical psychiatry in civilian life and of battle neurosis during the first world war made him a specially useful addition to the neurological staff. He took great interest in devising psychometric tests for detecting loss of mental capacity after head injury, and the large number of reports he made are carefully preserved for reference; these are still of great value in the treatment and care of those many soldiers and airmen who when convalescent from brain wounds were studied by Dr. Reynell. He was a natural physician and never failed to take extra time and trouble if by so doing he could help his

patients or colleagues. He had the highest ideals and his conscientious devotion to duty never faltered. We who worked with him came to admire his philosophy and to enjoy his friendship. His death brings a feeling of personal loss and deep regret that we shall not again meet to take part in the stimulating discussions we remember so well. One cannot think of Rupert Reynell without picturing him at home with his wife and family, of whom he was rightly so proud, and we can only send them our deepest sympathy.

JOHN ROWAN, M.B., F.R.F.P.S.

The pupils of Edward Nettleship spread throughout the world of ophthalmology for many years at the end of the nineteenth century. One of the most loyal was John Rowan, who died suddenly on March 17 at his home near Prestwick, where he retired about ten years ago. He was born in Greenock, and all his life he was influenced by the traditions of the West of Scotland and the Firth of Clyde. He graduated M.B., C.M. in the University of Glasgow in 1889, and was subsequently senior house-surgeon at the Greenock Royal Infirmary. At an early age he was attracted towards the study of ophthalmology as a specialty, and he worked in London, Dublin, Göttingen, Paris, and Berlin. At the old Moorfields, in Moorgate, he worked as a clinical assistant with Nettleship, and this led to a life-long association. To the last, Rowan was deeply interested in a family affected with retinitis pigmentosa and cataract, whose forebears from Devonshire had been traced out by Nettleship, and some of whose descendants were resident in the Glasgow area.

After his training period he returned to the Glasgow Royal Infirmary, and was ultimately appointed surgeon to the Ophthalmic Institution. He carried out his clinical work with patience and integrity. His passing will be a loss to many correspondents in all parts of the world. He had a gift for prolonged friendship, and was at his best when entertaining his chosen companions on the grouse moor or on the golf course. He admired and loved the out-of-door life, and brought to these interests the intensity of study characteristic of the townsman.

Dr. Rowan was elected a Fellow of the Royal Faculty of Physicians and Surgeons in 1900, and represented his colleagues on various boards of management until the end. At the annual meeting of the British Medical Association in 1922 he was vice-president of the Section of Ophthalmology. He contributed several carefully thought out papers to the literature of his chosen specialty, and he was considered to be a first-class clinical observer. Although he retired from active practice over ten years ago, he retained an active interest in the developments in ophthalmology in Glasgow. In later years he was rarely seen at medical society meetings; nevertheless, we have suffered a great loss in the passing of a man who could claim as his personal friends colleagues of the calibre of Nettleship, Treacher Collins, and Critchett.—W. J. B. R.

Medical Notes in Parliament

National Health Service Act

Mr. BOSSOM on March 18 inquired whether Mr. Bevan was yet satisfied that he would be able to provide the medical services proposed in the Health Service Act.

Mr. BEVAN replied that he certainly saw no reason why the Service should not start in the manner always contemplated.

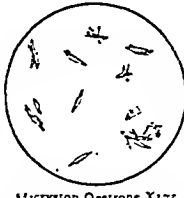

Disclosure of Service Records

Dr. MORGAN, during the discussion of the Air Estimates on Report on March 15, raised the subject of the disclosure from R.A.F. records of medical information on personnel who have left the Air Force. He said that sometimes Service departments, including the Royal Air Force, gave information to other Government Departments which were opposing claim and the men might thereby be prevented from obtaining employment, yet trade unions which asked for such information confidentially and were willing to pledge themselves never to abuse the disclosure of the medical record of any man were refused such information. In one Government Department the grant of such information had been conceded 25 years

ago and had since then worked admirably in the interchange of medical information between medical officers of the Department and of the trade union concerned. He asked the Royal Air Force to find a way by which such information could be given to the man to enable him to get justice in any future claim in which he might be involved. The Government might answer that if it disclosed this information to one person it would have to disclose it to insurance companies and other concerns for purposes which a Government Department might not consider legitimate. But a Department could impose restrictions on the disclosure of confidential information which would ensure that such disclosure was not abused while at the same time giving the man the opportunity of dealing on equal terms with the Service department. Dr. Morgan added that he did not demand an immediate answer to the point he had raised.

University Votes

When the House of Commons went into Committee on March 16 Mr. PEAKE challenged a proposal to abolish the university vote. He recalled that the Speaker's Conference had recommended the maintenance of university representation and methods of election. Mr. Peake contended that the case for the abolition of university seats was now weaker than it ever had been because university education was open to all who had talent, and in future 90% at least of graduates would be drawn from the ranks of the elementary schools. There was nothing undemocratic in giving extra representation to the best-educated section of the people. He asserted that the general election had not caused any part of the recommendations made by the Speaker's Conference to lapse.

Mr. PICKTHORN said that if the rule of "who pays the piper calls the tune" was to be exercised excessively by the Government in regard to the universities the effect was bound to be intellectually and scientifically bad. It was more than ever important that universities should have two channels of communication in Whitehall and Westminster. If the University Grants Committee became the only channel of communication the danger to academic independence would be overwhelming. The Government proposal was a blow at the learned professions.

Mr. HERBERT MORRISON denied that there had been any breach of undertaking by the Government. He agreed that a high proportion of university graduates now came from the elementary schools on scholarships, but to argue that this ought to give the House a bias in favour of this form of plural voting and of the separate representation of the universities was very wrong. The Government took the course which it did because it sincerely believed that it was inappropriate to have a Parliamentary representation which was not in accord with properly conceived democracy.

Mr. R. A. BUTLER, speaking for the Conservative Party, said that when that party was returned to power university representation would remain a feature of the House.

Mr. EDE said this was the last fancy franchise which remained and the Government believed it was high time that it was wiped out.

On a division the proposal to abolish the university seats was approved by 323 to 203.

Silicosis

Mr. GAITSKELL announced on March 22 that the number of new cases of silicosis in miners was 5,821 in 1945, 4,426 in 1946, and 3,800 (provisional) in 1947. The main precautions were (a) the suppression of all forms of dust in the mines, (b) medical and x-ray examinations of mineworkers on entry and periodically thereafter, (c) after-care of the men affected, including medical attention, and (d) their placing in suitable alternative employment with pre-employment training where necessary. These matters covered the responsibilities of many Government Departments, and progress in the formulation of comprehensive arrangements was being stimulated and coordinated by the National Joint Pneumoconiosis Committee. Four subcommittees were engaged on these main features of the problem each with a chairman from the Department mainly responsible. The National Coal Board and the National Union of Mineworkers were also represented. Dust prevention measures, already highly developed in South Wales, were being improved and extended in each coal division through the National Coal Board, and the National Union of Mineworkers were represented. A medical rehabilitation centre was also being provided by the Miners' Welfare Commission.

Previously, on March 18, Mr. Gaitskell said that although increased mechanization might produce increased quantities of airborne dust, in the present state of medical knowledge it was not possible to say whether the quantity or the quality of the dust was the most important factor in producing the disease. This was one of the main aspects of the problem on which the

Pneumoconiosis Research Unit was engaged. In these circumstances the National Coal Board were adopting measures to suppress as far as possible all forms of dust in the mines. These measures included wet cutting, water infusion, and spraying. Mr. Gaitskell added that far more work of this kind was done in South Wales than anywhere else.

Atomic Warfare and Civil Defence

Sir JOHN ANDERSON on March 22 opened the discussion on the organization of civil defence. He referred to shelter policies and said account ought to be taken of the possible effects of atomic bombs. The consequences of the explosion of an atomic bomb were first the blast, secondly the risk of what was called flash burn, which was burning by the radiation of heat, thirdly radiation, and lastly the problem of contamination. Except at a very short distance from the centre of an atomic bomb explosion the blast wave presented the characteristics of the wave following an ordinary explosion. It might be more violent but was not different in kind. There seemed no reason why a system of surface shelters should be rejected because of the atomic bomb. Flash burns caused many casualties at Hiroshima and Nagasaki, but the flimsiest protection—a sheet of brown paper—sufficed to prevent injury. But to protect against radiation considerable thicknesses of resistant material which need not be of solid structure would have to be interposed between the explosion and the people to be protected. For protection against radiation research would be required to determine the best kind of material for covering of sandbags would suffice. It would not be easy to decide when it would be safe for persons who had suffered no injury to emerge from a shelter. The first need would be to ensure an ample supply of simple detectors, which he believed could be provided cheaply and for use by shelter warden.

While radioactive material might be widely dispersed after an explosion a great deal of the activity would die away after a matter of hours or probably in less than a matter of days. If the occupants of shelters could be provided with suitable footwear and gloves it would be safe for them to traverse a considerable area which was still contaminated. If the explosion had taken place high above the ground all the radioactive material might be carried into the upper atmosphere, but if the explosion was on the ground or beneath the surface radioactive material might be widely dispersed and extremely difficult if not impossible to remove. An authoritative decision on shelter policy based on adequate knowledge should be made beforehand, and he suggested that a statement on policy should not be long delayed.

Major VERNON said that the Bikini experiments showed that an atomic bomb exploding under water produced about a million tons of radioactive water in the form of rain, spray, and mist. Ships over which that radioactive cloud had passed were still radioactive after eighteen months.

Cmdr. NOBLE said it had been discovered that the effect of the atomic bomb was limited. It would therefore be sensible to have hospitals, factories, and power stations dispersed so that if an atomic bomb fell only one of them would be affected. He asked for a comprehensive plan for dispersal throughout the country.

Squad-Ldr. KINGHORN said the House should realize that bacteriological warfare could take place and that the defence was in the Commonwealth. Something could be done now to give some kind of Empire and Colonial dispersal.

Government Reply

Mr. YOUNGER, replying for the Home Office, said that if the Government perfected and put into skeleton form a complete system of civil defence it would profoundly affect all peacetime commercial, economic, and social activities. They had to strike a balance between being caught entirely unprepared and developing a large defence system too soon. In war there was an immense advantage for the side which went into production last. They must have basic research and a clear idea of the problem before they put any great and costly machinery into operation. There had been an intensive analysis of the shelters in Germany and of the atomic bombing in Japan. Deep protection against atomic warfare. He knew of a number of shelters in various parts of the country seemed to provide good shelter protection continued. He detailed the arrangements made for the organization and planning of civil defence. The Emergency Medical Service and other organizations would have to be included. The Emergency Medical Service would be based largely upon the National Health Service with the co-operation in certain respects of the local authorities. In peacetime all local services would be recruited and administered locally. Training schemes would be devised centrally.

under Sir John Hodsell. He assured the House that the Government and its advisers were fully alive to the problems raised in the debate but some unknown factors still defied assessment and he must ask for further patience. The Government had not underestimated the importance of proper preparation in this sphere of defence.

Voluntary Hospitals Outside the Act

Mr. BEVAN issued on March 25 the following list of voluntary hospitals in the London area which had been disclaimed from the provisions of the National Health Act: the French Hospital and Dispensary; the Italian Hospital; the British Dental Hospital; King Edward VII Hospital for Officers; Royal Masonic Hospital; Star and Garter Home, Richmond; Scio House Hospital for Officers, Putney; Hurlingham Lodge Auxiliary Hospital; Hawthorne Christian Science House, Hampstead; Stanborough's Hydro, Watford; St. Andrew's Hospital, Dollis Hill; Hospital of St. John and St. Elizabeth; St. Vincent's Orthopaedic Hospital, Pinner; St. Saviour's Hospital; St. Joseph's Institute, N.9; St. Joseph's, E.8; St. Anthony's Hospital, Cheam; St. Veronica's, S.W.14; St. Michael's, Worcester Park; Hostel of St. Luke, W.1; St. Raphael's, Brentford; St. Raphael's Colony, Potters Bar; Pield Heath House; St. Teresa's, Wimbledon; Hostel of God, Clapham Common; Home of Compassion, Thames Ditton; Convent of Our Lady Nursing Home, Hillington Court; St. David's Home, Ealing; Etloe House, E.10; London Clinic for Psycho-analysis; Catholic Nursing Institute; Manor House.

The Minister and the B.M.A.

Mr. BEVAN told Sir THOMAS MOORE on March 25 that he had taken note of the decision of the British Medical Association on March 17 not to enter the new Health Service on July 5 unless substantial changes were made in the Act. Asked what further steps he proposed to take in the matter Mr. Bevan referred Sir Thomas to a reply given to Mr. Lipson on Feb. 19. This reply was reported in the *Journal* of Feb. 28 (p. 420).

When asked by Mr. BOSSOM on March 25 what steps he proposed to bring into operation the new Health Service without the co-operation of the medical profession, Mr. BEVAN replied, "I cannot accept the assumption underlying the Question."

N.H.S. Building Priorities

Sir ERNEST GRAHAM-LITTLE asked Mr. Bevan on March 25 to indicate the priorities which could be given in providing the buildings necessary for fulfilment of the National Health Service Act, 1946, including health centres and hospitals. Mr. BEVAN's answer was that only the most urgent needs could be met at the moment, but when conditions permitted provision would be made for the development of all services under the Act.

Universities and Colleges

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH NATIONAL HEALTH SERVICE ACT

At a meeting of the Royal College of Physicians of Edinburgh held on March 15 the following resolutions were adopted and it was determined that they should be communicated to the Prime Minister and to the Press:

Since its incorporation by Royal Charter in 1681, the Royal College of Physicians of Edinburgh has endeavoured to fulfil the purposes for which it was founded, namely, to consolidate the medical profession and to improve its standard of knowledge; to advance medical learning and science; and to promote by all means in its power the good health of the nation.

The Royal College of Physicians of Edinburgh shares the desire of the entire community for a National Health Service which will afford to the people the highest standard of medical service attainable. It views with disappointment and disquiet the failure of the negotiating parties to reach agreement.

The College is of opinion that the overwhelming vote of every section of the medical profession disapproving of the National Health Service Act, 1946, in its present form can only be explained by the fear that professional freedom is gravely endangered. The essential fear centres round the power of the Minister to alter by order or regulation the fundamental terms of service of the medical profession.

The College urges in the national interest that negotiations should be resumed and that the matters in dispute be re-examined and adjusted so that the profession will feel able to co-operate with confidence in the development of the comprehensive service desired by all.

Medical News

Course for Midwife-Teachers

The Royal College of Midwives will hold a four-months course starting on Aug. 4 for the training of midwife-teachers. The Ministry of Health is offering 15 scholarships of £65 each. Applications for scholarships must be returned before April 17. Further information may be obtained from: The Central Midwives Board, 73, Great Peter Street, London, S.W.1; or The Royal College of Midwives, 57, Lower Belgrave Street, London, S.W.1; or The Ministry of Health, Whitehall, London, S.W.1.

Edinburgh Refresher Course

A fortnight's refresher course at Edinburgh University begins on Monday, May 3, at 9 a.m. It is intended primarily for demobilized medical officers (Class II) and for insurance practitioners. Fee for graduates not claiming expenses from Government sources, 10 gns.

Trade Union Pressure

According to the *Daily Express* (March 22) the Surrey Federation of Trades Councils has empowered its executive to ask Surrey doctors if they intend to work in the new Health Service—"Then the federation plans to advise trade unionists to transfer to the panels of doctors who will work the scheme."

Recruitment and Training of Nurses

The "Ten" group has submitted to the Minister of Health its comments on the Working Party's Report on the Recruitment and Training of Nurses. The group consists of 10 State-registered nurses; they are anonymous. In order to define the duties of nurses the group believes that it is primarily necessary to analyse the needs of patients, for, as it points out, in recent years these have changed, and the patient has often come to be in the care of many individuals in contrast to the one or two in former times. These include doctors, nurses, medical auxiliaries, and domestic staff. The group suggests that the services of existing assistant nurses should be retained, but that the Roll of Assistant Nurses should be closed at a given date. It believes that the candidates to the nursing profession should be grounded in basic sciences before being admitted to hospital training, and it agrees with the Working Party that student status is a necessary prerequisite to professional status.

Welsh Tuberculosis Services

The Minister of Health and other officers of the Ministry received to-day representatives of the Welsh Regional Hospital Board (Sir Frederick J. Alban, Prof. R. M. F. Picken, Alderman the Rev. Digwel Thomas, Mr. Thomas MacDonald, Mr. W. J. Canton, Mr. H. T. Edwards, Alderman Tom Evans, and the Assistant Administrative Medical Officer and Secretary) on March 17 to discuss the proposal of the Regional Board to set up a separate hospital management committee to administer the tuberculosis service in Wales and Monmouth. The Minister considered that the proposal of the Regional Board did not entirely conform with the intentions of the Act, and made certain alternative suggestions with a view to entrusting the day-to-day management of the tuberculosis institutions to the respective local management committees while continuing certain central functions under the aegis of the Regional Hospital Board.

Wills

Sir John Fraser, who was Principal of Edinburgh University, left £60,960. Dr. Walter King Hunter, formerly professor of medicine in Glasgow University, left £73,973; Dr. Wilfrid Hugh Roberts, of Buckfastleigh, £14,392; Dr. Joseph Foreman Berry, of Wigan, £12,995; and Dr. Elizabeth Hamilton Brook, formerly assistant county medical officer in Lancashire, £20,924.

COMING EVENTS

International Congress on Mental Health

We are asked to remind those who wish to attend the International Congress on Mental Health, which is to be held in London from Aug. 11 to 21, that applications can only be accepted after April 15 in exceptional cases and provided space permits. It is appreciated that the high total cost of attending the congress may deter some people from applying; a reduction of fees will be considered in such cases if a letter to that effect is forwarded with the form to the Congress Organizer, 19, Manchester Street, London, W.1.

Gastro-enterology

A postgraduate course in gastro-enterology will be held on June 14-18 at the Tenon Hospital, 4, Rue de la Chine, Paris, 20. Those interested should write to Dr. Viguié at that address.

Institute of Hospital Administrators

The annual conference of the Institute of Hospital Administrators will be held at Caxton Hall, London, S.W., on Friday and Saturday, April 9 and 10. On April 9, at 2.15 p.m., the conference will be opened by Sir Hugh Lett, Bt., C.B.E., F.R.C.S., honorary secretary, King Edward's Hospital Fund for London. At 2.30 p.m. a paper on "Hospital Administration in the National Health Service" will be read by Mr. F. Messer, M.P., chairman, North-West Metropolitan Regional Hospital Board, and the subsequent discussion will be opened by Mr. George Watts, secretary, Oxford Regional Hospital Board, and Mr. F. J. Ingram, clerk and steward, Mapperley Hospital, Nottingham. On April 10, at 10 a.m., papers will be read on: "The Hospital Administrator's Conditions of Service": (1) "Superannuation under the National Health Service" by Mr. A. E. Hickinbotham, assistant secretary, Ministry of Health, and (2) "The National Health Service Whitley Machinery" by Mr. S. W. Mayne, assistant secretary, Ministry of Health. Discussions on the two subjects will be opened by Mr. G. Hurford, house-governor, Queen Elizabeth Hospital, Birmingham, and Mr. John Griffith, house-governor, Canadian Red Cross Memorial Hospital, Taplow, Bucks, respectively. At 2.30 p.m. a paper on "The Training and Qualification of the Hospital Administrator" will be read by Mr. C. G. Rolliston, president, the Institute of Hospital Administrators, and the discussion will be opened by Mr. F. A. Lyon, administrator, the Seamen's Hospital Society, Greenwich, and chairman, Examinations Committee of the Institute of Hospital Administrators.

On April 9, at 7.30 p.m. for 8 p.m., at the Savoy Hotel, London, there will be a reception and buffet supper (tickets, £1 ls. each, excluding wine).

Tuberculosis Association

A meeting of the Tuberculosis Association will be held at Brompton Hospital, London, S.W., on Saturday, April 10, at 10 a.m., when there will be demonstrations by Dr. Clegg, pathology of tuberculosis bronchitis, and Miss Reed, physiotherapy in chest disease. Medical and surgical clinical demonstrations and radiological demonstrations will follow. At 2 p.m. communications will be submitted by Dr. A. M. C. MacPherson, on "Late Follow-up of a Group of Children with Primary Tuberculous Lesions"; by Dr. F. H. Young, on "The Successive Use of Artificial Pneumothorax, Phrenic Interruption and Pneumoperitoneum"; and by Dr. A. T. M. Roberts, on "The Late Results of Extrapleural Pneumothorax."

Maudsley Hospital Medical School

Dr. J. G. Greenfield, F.R.C.P., will deliver a special lecture on "The Pathology of Encephalitis" at the Institute of Psychiatry of the British Postgraduate Medical Federation at Maudsley Hospital Medical School, Denmark Hill, London, S.E., on Friday, April 16, at 2 p.m. The lecture is open, without charge, to postgraduate medical students and others interested.

Medical Library Association

The 50th anniversary of the founding of the Medical Library Association, as well as its annual meeting, will be held in Philadelphia on May 28-30. Further information may be obtained from the Secretary, Academy of Medicine, 288, Bloor Street West, Toronto 5, Ontario, Canada.

Legal, Social and Industrial Medicine Congress

The twenty-fourth Congress of Legal, Social and Industrial Medicine will be held at Lausanne, Switzerland, from May 21 to 23, under the presidency of Prof. Reinbold. The secretary-general, Prof. Muller, 14, Avenue Friedland, Lille, France, will give all necessary information to those interested.

SOCIETIES AND LECTURES**Sunday**

LONDON JEWISH HOSPITAL MEDICAL SOCIETY.—At London Jewish Hospital, Stepney Green, E., April 4, 3 p.m. "The Workshop of a Novelist's Brain," by Mr. Louis Golding.

Monday

WESTMINSTER HOSPITAL SCHOOL OF MEDICINE: MEYERSTEIN LECTURE THEATRE, Horseferry Road, S.W.—April 5, 5.30 p.m. Clinicopathological demonstration. Discussion: "Hypertension."

Wednesday

MEDICAL SOCIETY OF THE L.C.C. SERVICE.—At St. Charles' Hospital, St. Charles' Square, Ladbroke Grove, London, W., April 7. Clinical meeting.

ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE, 28, Portland Place, London, W.—April 7, 3.30 p.m. "Problems of Adolescent Behaviour," by Dr. Doris Odum.

Thursday

FACULTY OF HOMOEOPATHY.—At the London Homoeopathic Hospital, Great Ormond Street, London, W.C., April 8, 5 p.m. "The Treatment of Certain Heart Conditions by Homoeopathy," by Dr. D. M. Borland.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN, 17, Bloomsbury Square, London, W.C.—April 8, 7.30 p.m. "Varicose Veins," by Mr. F. Rowden Foote.

Friday

BIOCHEMICAL SOCIETY.—At University College, Dublin, April 130 p.m. 266th Meeting. Papers will be read.

Saturday

ROYAL SANITARY INSTITUTE.—At King Alfred Baths, Hove, April 10, 10.30 a.m. "The Sterilization of Sea-water Baths with Special Reference to the Ozone Treatment." Paper by Dr. N. E. Chadwick.

APPOINTMENTS

William Henry Newton, M.Sc., M.D., D.Sc., has been appointed professor of physiology in the University of Edinburgh.

Prof. Newton was born in 1904 and was educated at Manchester University. He graduated with first-class honours in physiology in 1925, and held the Plac Scholarship in physiology in Prof. Raper's department. He qualified M.B., Ch.B. in 1929 and proceeded M.D. in 1934. From 1930 to 1934 he worked under Prof. Lovatt Evans and took the London D.Sc. in 1930. From 1932 to 1934 he was acting head of the physiology department at University College, which he left to take the George Holt Chair of Physiology at Liverpool University. He has published a number of papers on the physiology of pregnancy, and is on the editorial board of the *Journal of Physiology*.

BIRTHS, MARRIAGES, AND DEATHS**BIRTHS**

Browlee.—On March 9, 1948, at 9, Grosvenor Street, Edinburgh, to Mary, wife of T. J. Browlee, F.R.C.S.Ed., a son.
Wright.—On March 15, 1948, at Liverpool Maternity Hospital to Sue, a daughter. M.B. Ch.B. (née Richardson) wife of Dr. Frank B. Wright, a daughter.

DEATHS

Bromley.—On Jan. 24, 1948, as the result of a fall, Francis Edward Bromley, L.M.S.S.A., of 24, Orchard Street, Canterbury, aged 80.
Burditt.—On March 15, 1948, at Penarth, Myler Bridge, Falkmouth, Cornwall, Ralph Austin Burditt, M.R.C.S., L.R.C.P.
Mazze.—On March 11, 1948, Katie, wife of Dr. H. E. Mazze, 19, York Mansions, London, S.W., R.I.P.
Meeaw.—On March 17, 1948, at Lee Park Lodge, Blackheath, S.E., William Meeaw M.B., B.Ch., B.A.O., aged 64.
Mellor.—On March 16, 1948, at Mill House, Feltham, Robert William Mellor M.R.C.S., L.R.C.P., D.P.H.
Moore.—On March 16, 1948, at South Lodge, Hambury, Bristol, Clifford Arthur Moore M.S., F.R.C.S.
Muirhead.—On March 15, 1948, at Nod's Folly, Mill Lane, Earley, Berks, Ilay Burns Muirhead, M.D., aged 94.
Norman.—On March 13, 1948, at 8, Ayleyn Road, West Dulwich, Herbert James Norman, M.B., Ch.B.Ed. D.P.H., Medical Superintendent of Camberwell House, aged 67.
Potts.—On March 13, 1948, at Bower Cottage, Maidstone, George Potts F.R.C.S., late Major R.A.M.C., T.A., aged 71.
Rowan.—On March 17, 1948, at Whitechapel, Monkton, Ayrshire, John Rowan M.B. C.M.Glas., F.R.F.P.S.Glas.
Smith.—On March 12, 1948, at a Glasgow Hospital, Angus Dalrymple Smith F.R.C.S.Ed., of 3, Millgate, Richmond, Yorks, aged 47.
Todd-White.—On March 12, 1948, at Broomhills, Broomhill Road, Woodford Green, Arthur Thomas Todd-White, M.R.C.S., L.R.C.P., aged 73.
Williams.—On March 8, 1948, David Owen Williams, M.B., Ch.B., of Clwyd Hall, Glandyff, Cards, aged 77.

EPIDEMIOLOGICAL NOTES**Anti-cholera Vaccination Requirements**

An Order which came into force in Italian Somaliland on Oct. 25, 1947, directs that: (1) every person entering the territory of Somalia from Egypt, India, or Pakistan, other than a person in transit by air, shall be in possession of a certificate signed by a recognized medical practitioner stating that he has received a second inoculation against cholera not more than six months and not less than six days prior to the date of entry; (2) every person in transit by air through the territory of Somalia from Egypt, India, or Pakistan when not in possession of a valid certificate shall be subject to medical examination and will be allowed to proceed unless upon such examination he is suspected to be suffering from cholera.

Notification of Measles and Whooping-cough

A fee of 2s. 6d. instead of 1s. will now be paid for notifying the medical officer of health of a case of measles or whooping-cough met with in private practice. Though the compulsory notification of these diseases was regarded as likely to be temporary when it was introduced during the war, the Minister of Health considers that it should be retained, and he has therefore made the notification fee conform to the statutory rate.

Discussion of Table

In *England and Wales* an increase occurred in the incidence of whooping-cough 351, acute pneumonia 139, and dysentery 29, while a decrease was recorded for measles 339, scarlet fever 42, and diphtheria 27.

The notifications of whooping-cough over the past three weeks have been at the highest level since 1941. During the week under review the largest rises were those of Warwickshire 85 and Surrey 71. No large fluctuations occurred in the local returns of acute pneumonia, but a small increase was recorded in most areas.

After rising for seven consecutive weeks a fall was reported in the number of notifications of measles; the largest decreases were those of Northamptonshire 94, Gloucestershire 91, and Lincolnshire 91. Only small variations occurred in the local returns of scarlet fever; the largest was an increase of 40 in Wiltshire. The only feature of note in the returns of diphtheria was a decrease of 17 in Lancashire.

Two new outbreaks of dysentery were notified during the week, one involving 43 persons in Berkshire, Abingdon M.B., and the other 29 persons in Glamorganshire, Cardiff C.B. The other large returns of dysentery were Yorkshire West Riding 37 (Sheffield C.B. 23, Brighouse M.B. 10); Lancashire 28; and London 23.

The only areas with more than one notification of acute poliomyelitis were London 4 (St. Pancras 2); Wiltshire 2; Middlesex 2; and Warwickshire 3 (Birmingham C.B. 3).

In *Scotland* a fall in the number of notifications was recorded for measles 161, scarlet fever 28, cerebrospinal fever 12, and diphtheria 10, while a rise occurred in the incidence of acute primary pneumonia 43 and dysentery 35. The largest returns of dysentery were in the cities of Edinburgh 18, Glasgow 14, Paisley 14, and Aberdeen 10. The rise in the incidence of pneumonia was contributed by the western area.

In *Eire* an increase occurred in the incidence of diarrhoea and enteritis 16 and pneumonia 16, while a decreased incidence was reported for whooping-cough 22. Three-quarters of the cases of diarrhoea and enteritis were notified in Dublin C.B. Whooping-cough was slightly less prevalent in all areas except Dublin C.B., where a rise of 9 occurred.

In *Northern Ireland* a decrease of 14 was recorded in the notifications of scarlet fever.

Quarterly Return for Scotland

During the December quarter the birth rate was 19.5 per 1,000, being 2.6 below the rate for the corresponding quarter of 1946 but 1.3 above the average of the five fourth quarters of 1942-6. The infant mortality was 57 per 1,000 registered live births—1 more than that for the December quarter of 1946 but 6 less than the five years' average. The maternal mortality was 1.4 per 1,000 total births and was the lowest rate recorded for any quarter. The general death rate was 12.3 per 1,000, and was 0.4 below the average of the five preceding fourth quarters. The death rate from all forms of tuberculosis was 77 per 100,000 and that from respiratory tuberculosis was 67. The former was 2 lower than that for the fourth quarter of 1946, and the latter was the same as in that quarter, but they were respectively 6 and 9 above the five years' average. The largest number of deaths from epidemic diseases were 29 from influenza, 21 from cerebrospinal fever, 16 from measles, 10 from whooping-cough, and 9 from diphtheria.

The provisional return for the whole of 1947 shows that the birth rate of 22.0 per 1,000 was the highest recorded since 1923. The infant mortality was 56 per 1,000 live births; this rate was 2 above that for 1946, and with this exception it was the lowest rate ever recorded in Scotland. Maternal mortality was 2.0 per 1,000 total births and was the lowest rate ever recorded. The general death rate was 12.9 per 1,000 and was 0.3 above the average of the five preceding years. The death rate from all forms of tuberculosis was 80 per 100,000, and for respiratory tuberculosis the rate was 66. These rates were 3 and 7 respectively above the average of the five preceding years. Deaths from epidemic diseases included 345 from influenza, 223 from whooping-cough, 130 from acute poliomyelitis and polio-encephalitis, 88 from cerebrospinal fever, 57 from measles. Only 44 deaths were attributed to diphtheria, the smallest number ever recorded in Scotland. In 1940 deaths from diphtheria numbered 676. Deaths from diarrhoea and enteritis at ages under 1 year numbered 1,123.

Week Ending March 20

The notifications of infectious diseases for England and Wales during the week included: scarlet fever 1,847, whooping-cough 3,304, diphtheria 173, measles 10,034, acute pneumonia 963, cerebrospinal fever 49, acute poliomyelitis 20, dysentery 170, paratyphoid 2, and typhoid 6.

No. 11

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended March 13.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) *England and Wales* (London included), (b) *London* (administrative county), (c) *Scotland*, (d) *Northern Ireland*, (e) *Eire*.

Figures of Births and Deaths, and of Infant Mortality, for the week and those for the corresponding week last year, for: (a) The 126 great towns in England and Wales, (b) *London* (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland. A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

|| Includes puerperal fever for England and Wales and Eire.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Pelvic Osteitis after Prostatectomy

Q.—What is the pathology of the pelvic "osteitis" which occasionally follows prostatectomy? Does the inflammatory tide always stop at the ischial tuberosities? Is there any specific treatment other than penicillin in the febrile phase? What is the average period before, say, office work is (a) safe, and (b) comfortable? Are the radiological appearances distinctive?

A.—Pelvic osteitis following prostatectomy appears to be a subacute infective process starting in the periosteum near the symphysis and spreading to involve the symphysis and a variable length of the pubic and ischial rami. The infecting organism is not known with certainty. It is probable that *Bact. coli* is the most frequent offender; *B. proteus* and staphylococcal infections have also been reported. The area of osteitis is almost invariably limited to the pubic and ischial rami, but very occasionally the process may extend further, and may even reach the acetabulum, when the hip-joint may, exceptionally, become involved. In a proportion of cases an abscess forms in the soft tissues and may discharge for a variable period. The diagnosis can be established by radiological examination, though changes will not usually be observed until the infection has existed for two months or so. The characteristic changes consist of rarefaction of the pubic bone and often of the ischial rami; the symphysis may be widened and often has a moth-eaten appearance. Later there is new bone formation subperiosteally, giving the appearance of short bony spurs. In the stage of healing the symphysis may become ankylosed by bone.

The disease is self-limiting, and full recovery of function is to be expected. Most forms of treatment have no effect on its course. This often applies even to penicillin, which in most cases has given disappointing results, probably because the organisms responsible are insensitive. If the pain and muscle spasms are severe the most satisfactory form of treatment consists in the application of a double plaster hip spica, which is retained for two to six months. Chemotherapy should of course also be tried, though its effects are uncertain. Apart from these measures the only active treatment that may be required is the drainage of local abscesses if they occur. The period before return to work can be advised is so variable that no general rule can be given. In some cases recovery is complete in two to three months; in others the symptoms persist for up to two years. A probable approximate average period of disability would be six months from the development of symptoms. It should be safe to resume sedentary work as soon as short walking distances can be covered without marked discomfort.

Inheritance of Cystinuria

Q.—What type of inheritance is concerned in the hereditary abnormality in metabolism which causes cystinuria?

A.—The inheritance of cystinuria is not very clearly established. One difficulty is that the metabolic anomaly may be present without the formation of calculi and so biochemical investigation is required for its recognition. Nor does it seem to be established whether there is a relation between the frank and very rare disease and the relatively common excretion of small amounts of cystine as found by some workers in otherwise normal people. There is, in fact, little to add to Garrod's account of 1923 (*Inborn Errors of Metabolism*, 2nd ed., Oxford University Press). It seems certain that in some families at least inheritance is dominant, for several instances of direct transmission through three generations have been proved. On the other hand it seems likely that in some families inheritance is recessive. There is a marked preponderance of males among affected persons. Thin's remarkable pedigree (Robson, *Biochem. J.*, 1929, 23, 1938) includes two large sibships of first cousins, with three marriages between them. This pedigree

has the unusual distinction of fitting either dominant inheritance or sex-linked inheritance (with a high rate of expression in heterozygous females), or, with rather less likelihood, recessive inheritance.

Cases for the Coroner

Q.—(a) In many cases "the coroner has the power of holding a court without a jury if, in his discretion, it appears to be unnecessary. In charges of murder, manslaughter, infanticide, deaths of prisoners in prisons, inmates of asylums or inebriates' homes, or of infants in nursing homes, he must summon a jury." Is this a true and proper statement of the law in these cases as it applies to-day?

(b) What operative deaths should be reported to the coroner? At some hospitals all deaths that occur within twenty-four hours of an operation are reported, while elsewhere it is held that unless the death occurs "on the table" the coroner is not notified.

A.—(a) In ancient times every inquest was held with a jury, but the Coroners (Amendment) Act, 1926, Section 13 (1) allows of the jury being dispensed with at the discretion of the coroner except in certain types of case. These exceptions include those mentioned in the question quoted above, and also cases of death due presumably to accident, poisoning, or disease of a kind notifiable to a Government Department—e.g., certain industrial diseases such as lead poisoning—or to a street accident, and of death occurring in circumstances which may be "prejudicial to the health or safety of the public or any section of the public." This last provision enables the coroner to direct attention forcibly to any state of things which constitutes a risk of further injury or death to persons exposed to such conditions.

(b) Under Section 75 of the Registration (Births, Still-births, Deaths, and Marriages) Regulations, 1927, it is the duty of the registrar to report to the coroner any case of a death occurring following an operation for dealing with the results of an injury, or any death occurring at operation or before the effects of the anaesthetic have passed off. A hospital may make a rule that any death occurring within twenty-four hours of operation should be reported to the secretary or house governor, or a coroner may express a desire that any such deaths should be notified to him, but such arrangements have no statutory basis. The important thing to remember, however, is that any death which appears to be unnatural or to suggest circumstances of special danger to health or life should be brought to the notice of the coroner, who should be given an opportunity of making such inquiries as he may think proper.

Intravenous Procaine Analgesia in Obstetrics

Q.—What are the advantages, the dangers, the technique, or the indications for intravenous procaine analgesia in obstetrics?

A.—Only a few comparatively small series of cases in which intravenous procaine has been used to relieve the pains of labour have been recorded, so the method is still in an experimental stage and it is not yet possible to assess its value, dangers, and limitations. The effect of procaine given intravenously is very short-lived, so it is necessary to give the drug by continuous infusion. In one technique 10 g. of procaine are dissolved in 1 litre of 5% glucose in water and the intravenous drip is begun as soon as "pains" become distressing even if the cervix is only two to three fingers dilated. The rate of administration at this stage averages about 1 ml. per minute, but it has to be varied from time to time according to the reactions and sensations of the patient. When full unconsciousness is required as for the birth of the head, the application of forceps, or repair of episiotomy, the "drip" is allowed to run freely. The total dose naturally varies with the speed and duration of the infusion, but one patient is recorded as having had as much as 8 g. in six hours, and another had 9.5 g. in nine hours.

Intravenous procaine seems not to depress uterine contractions to any extent, and the patient recovers consciousness very quickly when its administration is discontinued. The degree of relief of pain depends on the rate of infusion, and it is claimed that the patient can co-operate well in the second stage even when there is considerable dulling of consciousness.

Amnesia is poor, however. Although early reports do not include cases in which either mother or child has shown significant ill effect, it is clear that the method is not without danger. When the dose is sufficient to give maximum relief the patient often has convulsions, but their incidence is reduced by preliminary medication with barbiturates, which is advised as part of the routine. It is also important to exclude a drug idiosyncrasy by skin and eye tests before beginning the intravenous drip. If the risks are to be reduced to a minimum it would seem necessary for a skilled observer to be in constant attendance during the several hours of treatment, ready always to stop the infusion and to administer antidotes (phenobarbitone and adrenaline). For further details reference might be made to papers by F. M. Allen (*Amer. J. Surg.*, 1945, 283, 290; *Cur. Res. Anesth.*, 1946, 25, 1) and by K. Johnson and C. R. A. Gilbert (*Cur. Res. Anesth.*, 1946, 25, 133).

Curare and Smooth Muscle

Q.—What is the effect of curare on smooth muscle, with special reference to uterine muscle?

A.—The general view is that curare has no action on smooth muscle, but there is evidence that this requires modification. Cross and Cullen (*Anaesthesiology*, 1945, 6, 231) found that "intocostrin" (1 mg. per kg.) caused peristalsis to cease for some time and brought about a loss of intestinal tone. These observations were made in unanaesthetized dogs with fistulae. Curare is believed to act on skeletal muscle by blocking the action of acetylcholine on the motor end-plate, and, since the intestine and other forms of smooth muscle such as the uterus also appear to contract by acetylcholine action, it is likely that they will be paralysed to some extent as well. Normally, smooth muscle is unaffected by doses which paralyse skeletal muscle, but it is reasonably certain that occasional subjects will be found in whom the smooth muscle is also affected. Whitacre and Fisher (*Anaesthesiology*, 1945, 6, 124) describe the successful use of curare with cyclopropane anaesthesia in 100 operations for caesarean section. They make no mention of an effect on the uterus.

Profuse Sweating in Acute Rheumatism

Q.—Can you suggest any treatment for profuse sweating in a case of acute rheumatism? A stout and flabby man aged 28 has had recurrent attacks of acute rheumatism lasting three months, with profuse bouts of sweating, tachycardia, and slight pyrexia. There is gross involvement of the endocardium of old standing. The pyrexia has settled and remained normal for over a month, and the heart rate at rest is 72, rising to 90 on effort, but the bouts of profuse sweating continue and cause anxiety.

A.—It is difficult to suggest any line of treatment in this case, but rest in bed or on a couch on a sunny balcony or similar situation for a long period appears to be advisable. No evidence is supplied on the sedimentation rate, which would be a guide to the presence of any active infective process. Endocrine disturbance is possibly responsible, but any specific line of treatment for this is hardly possible, though small doses of thyroid might be useful. General light massage may be helpful, and ultra-violet irradiation given cautiously, and beginning with very small exposure, should be tried. Vitamin C is usually deficient in these rheumatic conditions, and should be supplied. It is not stated whether salicylates are still being given; they might account for excessive sweating and should be stopped.

Lacrimal Hypersecretion

Q.—What is the best treatment for excessive secretion from the lacrimal gland as the result of exposure of the eye to cold or wind, especially when accompanied by high relative humidity? There is no sign of conjunctivitis or blockage of the nasal duct.

A.—Treatment is unsatisfactory. The excessive watering is probably due to hyperactivity of the lacrimal gland induced by the stimuli mentioned. Protective glasses may help. Drops of 1% sulphate 0.25% may likewise be useful where watering is persistent.

NOTES AND COMMENTS

Skin Graft for Leg Ulcer.—Dr. D. REID TWEEDIE (Sungei Siput, N., Perak) writes: In the reply (Jan. 24, p. 183) to the question on this subject there is no mention of penicillin dressings. I have yet to find the tropical ulcer, even of many years' duration, which does not respond to penicillin lotion. The first dressings are strong, 20,000 units per ml., and the later ones weak, 5,000 units per ml. The base soon becomes pink and healthy and in a few weeks granulates to the surface; then a whitish epithelium grows in from the edge and the ulcer is healed.

Aseptic Inoculation Technique.—Dr. R. S. TAYLOR (Paris) writes: With reference to the question and answer under this heading (Feb. 28, p. 425), many years ago, perhaps thirty, I saw in the *Journal* a method of sterilizing syringe and needle at the bedside with primitive materials—viz., a teaspoon, some oil (olive for preference, butter if nothing else), a candle, a bread crumb.

Put the bread crumb in the oil in the teaspoon and hold over the candle till the bread crumb chars. The oil may then be sucked into the syringe as many times as necessary. I have not tried to make a culture from a syringe or needle treated in this way, but do not think that any germ, even one which apparently enjoys being boiled, would consent to function after being charred. The syringe may be cleared of oil with a little ether.

Cataract.—Dr. E. E. D. GRAY (Anerley, London, S.E.) writes: I was interested in the questions and answers about cataract (March 13, p. 531). I have had operations on both eyes for cataracts. One result is unsatisfactory but the other is excellent. I am not able to give an opinion on parts (a) and (b), but about part (c) I can speak from experience. I can see 6/9 and J1 and I do not suffer from eyestrain on reading. As a physician I have no difficulty in using an ophthalmoscope. I am therefore able to do my ordinary work.

Car driving by day is a simple matter. I can judge distance by the size of familiar objects. Driving by night is altogether different. The familiar objects are not visible and I cannot judge the distance in front of me of the tail-light of a car or lorry. The lights also dazzle me. However, in the depth of the night when there is no traffic and the street lights are extinguished I can use my headlights and driving is almost as easy as in daylight. However, I avoid night driving as far as possible.

Nocturnal Frequency in Elderly Men.—Dr. E. GALLOP (London, S.W.) writes: The influence of habit is not mentioned in the answer to this query (March 13, p. 532). In the absence of obvious prostatic enlargement, infection, or loss of elasticity in an ageing bladder wall it is a factor which should not be disregarded. The timing of micturition is an easily conditioned reflex, but a few broken nights will upset it and nocturnal frequency soon becomes established, and then the bladder has to be retrained. This means putting up with discomfort for a few nights, which many will not tolerate when relief is so easy. A dose of n bromide and belladonna mixture on retiring will help as a urinary sedative until the new habit is formed.

Polish Children's Hospital.—The Polish Red Cross Society has decided to build a large modern hospital for children on the heights of Rakba near the Tatra mountains. The deplorable ravages wrought by the war in Poland have particularly affected the children, and such is the poverty of the land that no public or private funds are available for this necessary work. The Polish Red Cross Society is therefore appealing for funds, which may consist of money or of goods such as bedding and clothes. Any donations will be used exclusively for constructing and equipping this hospital, and they will be gratefully received by Mrs. J. Gorska, Polish Red Cross Society, 35, Roland Gardens, London, S.W.7.

Correction.—The remarks attributed to Dr. Irene Yates in the report of a meeting of the Section of Psychiatry of the Royal Society of Medicine (March 20, p. 558) were made by Dr. Sybille L. Yates.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY APRIL 3 1948

British Medical Association PROCEEDINGS OF COUNCIL

Wednesday, March 24

A meeting of the Council of the Association was held at B.M.A. House on Wednesday, March 24. Dr. H. Guy Dain presided, supported by the President (Sir Hugh Lett, Bt.), the President-elect (Sir Lionel Whitby), the Chairman of the Representative Body (Dr. J. B. Miller), and the Treasurer (Dr. J. W. Bone).

The deaths of four former members of the Council—Dr. J. B. Anderson, Dr. T. D. C. Barry, Dr. G. Y. Eales, and Dr. E. Lewys-Lloyd—were reported, and the Chairman was authorized to forward letters of condolence to their families.

Resolutions of Special Representative Meeting

The Council considered the resolutions of the recent Special Representative Meeting. Many of these reaffirmed the policy and course of action which the Council were already pursuing; others were referred for action to the Public Relations, the General Practice, and other committees.

On the resolution which condemned as grossly improper the bringing of pressure to bear upon individual doctors for political purposes to induce them to inform outside bodies of their intentions concerning the new service, it was agreed to bring the matter to the notice of the General Council of the Trade Union Congress, with which body the Association has a joint committee.

Reference was made to Sunday newspaper reports that doctors in Surrey were to be asked by the Surrey Federation of Trades Councils whether they intended to operate the Act, and it was added that this information was desired in order that all Surrey trade unions might advise their members to get on the lists of doctors who were taking part in the Service.

The Council unanimously passed a resolution condemning the action of the Surrey Federation of Trades Councils "as an improper attempt by one section of workers to bring economic pressure on another section to influence them in the exercise of a free decision granted by an Act of Parliament."

National Health Service

Dr. Vaughan Jones referred to statements published in newspapers in Yorkshire to the effect that Lord Addison was to be asked to act as arbitrator.

The Chairman of Council said that there had been no approach of any sort or kind from the Government. Such statements were the anticipations, intelligent or otherwise, of correspondents.

It was agreed that the present National Health Service Executive Committee, with the addition of four members of the Public Relations Committee who were not already Executive members, should handle the general conduct of the Council's work between meetings of the Council. It was pointed out that such work in the immediate future would be largely of a public-relations character.

Dr. Dain said that for the development of uniform action and as a temporary measure liaison committees of consultants were being set up. A large committee under the chairmanship

of Lord Horder had already been set up in London at the instigation of the Marylebone Division. That committee had passed a resolution stating that it considered it desirable to investigate the present Act with respect to the privileges and restrictions of the consultant and specialist section of the profession, and that the best possible legal opinion should be obtained to that end. It was agreed to make available to the London Liaison Committee the legal opinions already elicited when the subject was under consideration by the special sub-committee of the Negotiating Committee.

Consultant and Specialist Organization

Dr. J. A. Pridham, chairman of the Organization Committee, brought forward proposals for the formation within the Association of regional consultant and specialist committees and of a central committee which would take the place of the present Consultants and Specialists and Hospital Committees. He said that there would be general agreement with the idea that in the area of each Regional Hospital Board there should be a professional committee to represent the views of the profession on hospital and consultant and specialist services in the region. There was no statutory provision for the setting up of such committees as there was for local medical committees in the field of general practice. The majority of the members of such committees must be elected by practitioners engaged in consultant and specialist practice, and separate representation must be given to those of full medical staff status employed by hospitals within the region. The Organization Committee was proposing that not less than one-quarter of those elected to the committees by staffs of non-teaching hospitals should be part-time consultants and specialists. For the first year at all events the mode of election to these regional committees should be on the principle of representation of hospital staffs. After careful examination the conclusion had been reached that Branch machinery—in England and Wales, at any rate; in Scotland the circumstances were different—could not be effectively used in this work.

As for the central committee, whose function it would be to consider matters specially affecting those engaged in consulting or specialist practice, including matters referred from the regional committees, and all questions concerning hospitals, a majority of the members should be elected by the regional committees (the committee would be to some extent a replica from the consultant and specialist side, of the present Insurance Acts Committee), and there should also be representatives of the present Specialist Groups and of part-time consultants and specialists. (The proposals will be set out in detail in the Annual Report to be published in the Supplement of April 10.) The recommendations were supported by Mr. A. M. A. Moore and Mr. R. L. Newell, chairmen respectively of the present Consultants and Specialists and Hospitals Committees, but Mr. Newell made a plea that the word "hospital" should be incorporated in the name of the new committees. This plea found a good deal of support in the Council, but

Mr. Lawrence Abel, while agreeing that the committees must cover all aspects of hospital policy, suggested that the addition of the word "hospital" would make the name cumbersome.

An amendment to make the name "Regional Consultants and Specialists and Hospitals Committees" instead of "Regional Consultants and Specialists Committees" was defeated by 19 to 20, and a compromise was reached that the formal, though not the everyday, name of the new organization should be "Regional Consultants and Specialists (including Hospitals) Committees."

Speaking on the general question, Mr. Abel paid a tribute to Mr. Moore, Dr. Pridham, and Mr. C. E. Kindersley for the work they had done in connexion with this new set-up. He said that consultants hitherto had had no body at all to represent them democratically. He hoped that the new organization would be truly representative and that every consultant in the country would "look to Tavistock Square."

Dr. J. B. Miller asked whether it was not the fact that the percentage of consultants in the Association was greater than the proportion of general practitioners, and was informed that that was so.

Dr. Vaughan Jones hoped that with the establishment of these committees there would be no attempt to supplant Branch organization, in which both consultants and general practitioners could meet.

On the details of constitution Mr. Newell on behalf of the Hospitals Committee offered some criticisms. One was that medical superintendents should not, as was proposed, be specially represented on the regional committees but should be eligible for election as specialists in administration, and Dr. J. B. W. Rowe suggested representation of industrial medical officers, but this proposal was not accepted. The Council agreed that the proposals for regional committees should not apply to Scotland until the Scottish Committee had had a further opportunity of formulating its views, and that as regards the new Central Committee provision should be made for the appointment of not more than ten representatives of consultants and specialists in Scotland, the number and mode of appointment to be determined by the Scottish Committee and the Council.

The Council, having considered a petition of members of the Association for the formation of a Group of Venereologists, approved the establishment of such a Group composed of members engaged predominantly in practice in that field.

The Size of the Representative Body

Dr. Pridham, on behalf of the Organization Committee, proposed a recommendation for the reduction of members of the Representative Body to approximately 300, the Council to be instructed to submit a plan, with appropriate amendments to the by-laws, to give effect to such decision.

Dr. J. G. Thwaites objected to any diminution of numbers. The original idea was to have one representative for about 100 members, and that was a good basis to go upon. It seemed odd to diminish the representation because of the growth of the electorate. It was a healthy thing that as many representatives as possible should be appointed, for such people when they went back to their constituencies were good disciples of Association policy.

The Chairman pointed out that the House of Commons had had to face the same problem.

Dr. Pridham said that the basis would still be a minimum of one representative for each Division, but it seemed not unreasonable to cut down the representation of the large Divisions. Dr. E. A. Gregg thought that the case for making the optimum figure 300 was overwhelming. The governing considerations were the effectiveness of the Representative Meeting as a working body and also the limitation imposed by the size of the Great Hall of Association House or the halls available in provincial cities where the Annual Meeting might be held.

It was agreed, however, to refer back the proposal to the committee.

General Practice

Dr. S. Wand, chairman of the General Practice Committee, in order to bring the policy of the Association into line with the revised local authority part-time scale, moved a recom-

mendation that, where practitioners were requested to administer anaesthetics to insured persons receiving dental treatment as an additional benefit under the National Health Insurance Acts, a fee of from 30s. for each administration, depending on the length of operation and the anaesthetic used, should be paid. This was agreed to. It was also agreed that the fee for giving elementary lectures to the lay public on first-aid to the injured, home nursing, child care, and hygiene should be 1½ guineas.

Dr. W. E. Dornan, dealing with a reference in the General Practice Committee's report to fees for life insurance examinations, said that he had had complaints from doctors who did a fair amount of this sort of work that, although the Committee had obtained an increase in the fees payable, their income from relatively the same number of life insurance examinations had actually decreased. This was because of the large amount of insurances effected for between £100 and £250, for which the long-term examination fee was 1½ guineas and the short-term half a guinea. The insurance companies were now using the short form, and therefore the medical examiners were receiving less for the same amount of work.

Dr. Wand said that the short form entailed less than on third the amount of work. Dr. I. D. Grant said that the experience related by Dr. Dornan was not the usual one. It was only those dealing largely with industrial insurance who were using the short form, and the time taken over the short form was negligible as compared with the time taken over the long. He thought the General Practice Committee was to be congratulated on what it had achieved.

Insurance Practice

Dr. E. A. Gregg, chairman of the Insurance Acts Committee referred to the Maternity Benefit Regulations, 1948. The committee considered one or two of the provisions in the regulations to be objectionable and had brought them to the notice of the advisory committee, under the chairmanship of Sir Will Spens, which had been set up to consider and report on such representations. In one instance Sir Will Spens's committee had undertaken to consider the regulation in the light of the committee's objection, and in another a somewhat ambiguous wording had been cleared up.

Dr. Gregg reported that the National Insurance Deferment Trust had made an initial contribution of £400,000 to the Independence Fund.

Industrial Medicine

It was agreed to change the name of the Industrial Medicine Committee to the Occupational Health Committee and to widen its terms of reference to include "matters affecting the health of persons at work and the practice of medicine in industry and allied occupations."

Dr. Vaughan Jones brought forward recommendations for a scale of remuneration of part-time industrial medical officers. The scale included schedules for remuneration on an hourly per-week basis and on a sessional or visit basis. It was suggested in one quarter of the Council that the proposed rates were not properly related to the salary scales for whole-time industrial medical officers, but a motion to refer the matter was not seconded. A discussion developed on the advisability of basing remuneration on the size of the factory or on the length of sessions or on a combination of the two. The general feeling was that "timeage" was the only factor that really mattered, although in some factories a doctor might be expected to make himself acquainted with certain processes, for which special remuneration should be paid.

The recommendations were approved.

Public Health

Dr. James Fenton, chairman of the Public Health Committee, said that an agreement concerning salaries of mental hospital and mental deficiency institution medical officers had been negotiated with the local authority associations and the Mental Hospitals Association for such officers as were not covered by the Askwith awards. The increases were as follows: if the datum salary did not exceed £700, by 30% of that salary; if it exceeded £700 but not £1,000, by 20% of that salary; and if it exceeded £1,000, by 10%, provided that no officer should have an automatic entitlement to a total salary greater than

at produced by the addition to the maximum of the scale pay as at Sept. 3, 1939, for the position he occupied, of the appropriate percentage increase on the datum salary. The agreement was approved by the Council.

Dr. Fenton also reported that a further meeting had been held with Ministry of Health representatives to discuss the association's claim for a revision of fees payable to doctors killed in by midwives. The Ministry was unable to concede certain points, but increases in other directions were secured. He placed before the Council the proposals as amended, showing the improvement on the existing fees, and also how what had been conceded compared with the claim put forward. As was a matter of urgency the Chairman of Council, in anticipation of the present meeting, had given approval. The details will be found set out in the Annual Report of Council.

Since the document was issued, Dr. Fenton added, the draft regulations had appeared, and these departed in certain respects from the agreement arrived at with the Ministry. The Ministry as being interviewed on the subject on the following day. The Council endorsed the approval which the Chairman had given, and the negotiators, Dr. Fenton and Dr. Wand, were congratulated on their endeavours.

Association Finance

Dr. J. W. Bone (Treasurer) presented the financial statement for 1947. He said that the Association's buildings, after deductions for depreciation and amortization, were valued at 315,000. The investments stood at 171,000. The total assets were 1604,000. There was a handsome increase of 15,000 in subscriptions. The *Journal* showed a magnificent revenue of 162,000, and the profit on the *Journal*—27,749—was more than double the amount for the previous year. The warty journals and *Medical Abstracts* also showed satisfactory financial results. The income of the Charities Trust had risen from 7,500 to 11,500.

Dr. Bone said that the Finance Committee had considered a reference from the Annual Representative Meeting that the increase had arrived when an increase in subscription rates should be contemplated, but in the view of the Committee the financial position as disclosed by the annual accounts did not justify any immediate action in this respect. It might well be, in view of the greatly increasing expenses of the Association, that the raising of the subscription would have to be considered a little later.

The Council decided that an initial sum of 100,000 from association funds should be placed at the disposal of the Independence Fund.

A report by the Financial Hardship Committee, set up to consider what financial aid might be needed by practitioners should the present dispute be prolonged, was presented by Mr. A. Brown. The Committee had found it impossible at present to predict the extent of possible hardship, but it felt that the problem was not of such magnitude that it could not be dealt with adequately from available funds. The setting up of the Independence Trust had made further work by the committee unnecessary.

Public Relations

The Council discussed certain present and projected public relations activities. The suggestion was put forward that a mass meeting for the general public should be held at the Albert Hall on May 20, and this was welcomed in several quarters of the Council. It was also stated that a 20-page handbook giving chapter and verse, with appropriate quotations, for every point in the Association case was being prepared. Posters and leaflets would also figure in a large publicity campaign, anticipating the expected Government activity. Other methods of publicity were indicated.

Science

Dr. R. G. Gordon presented the report of the Science Committee. A recommendation was agreed to that the Sir Charles Hastings Clinical Prize for 1948 be awarded to Dr. J. G. Nathan, of Stoke-on-Trent, for his essay, "Body Weight as an Index of Toxaemia During Pregnancy."

Discussion took place on a proposal that in future an honorarium, in addition to first-class travelling expenses, be

paid to B.M.A. lecturers. This was opposed by Dr. Pridham, who pointed out how steeply the expenditure of the Association was rising, and said that no difficulty had been found in the past in obtaining first-class lecturers without this inducement.

A motion to refer back the proposal was lost.

The Council agreed that a special committee should be set up, along the lines of the Medical Curriculum Committee, to consider the preparation of a report on postgraduate education, but it did not proceed to appoint the committee at the moment.

The Association in Scotland

Dr. G. MacFeat, for the Scottish Committee, reported that some progress had been made with local authorities in Scotland concerning interim increases in salaries of whole-time members of the Public Health Service recommended by the Association.

He also stated that practitioners in the Highlands and Islands had held a meeting recently concerning their position under the National Health Service (Scotland) Act. Certain difficulties arose concerning the houses in which they lived and which belonged to the local authority. They were holding another meeting, and in the meantime it had been decided that the Scottish Negotiating Committee should be asked in any future discussions with the Department of Health to press for the appointment of a Highlands and Islands Standing Advisory Committee of the Scottish Health Services Council.

Ethical Business

Dr. Waterfield mentioned a communication which had been received from the Engineering and Allied Employers' National Federation concerning pre-employment examinations and disclosure of findings to examinees. The Occupational Health Committee, which had already considered the matter, held that when an industrial medical officer had examined a person with a view to employment there was no objection to the disclosure of his findings to the patient and to the patient's medical attendant when requested. The view of the Central Ethical Committee was that where applicants for employment were rejected on medical grounds by the works medical officer and desired to be informed of the reason for their rejection, provided there was no objection by the employing body, the medical officer should acquaint the patient's own doctor and the patient should be given the reason by his medical attendant.

Dr. Vaughan Jones considered that the disclosure should not be made by the patient's own doctor; the industrial medical officer should be allowed to state to the applicant in non-technical language the reason for his exclusion from employment. On the other hand, Dr. Thwaites and Dr. Grey considered that the information could most satisfactorily be given by the man's own doctor, who could give it with better understanding of the patient's personality and circumstances.

The general view of the Council was that the industrial medical officer should inform the patient only of his unsuitability for employment by reason of the occupation and that there should automatically be a reference to the patient's own doctor, who should be told the reason for the man's rejection.

British Commonwealth Medical Council

It was reported that the Council's invitation to the Branches and Medical Associations in the Dominions to co-operate in the establishment of a British Commonwealth Medical Council to foster a closer liaison between the profession in the United Kingdom and the Dominions had been warmly received, and the following bodies had agreed to appoint delegates to an inaugural meeting to be held in London during the current year: the Canadian Medical Association, the Federal Council of the Association in Australia, the New Zealand Branch, the South African Medical Association, the Medical Association of Eire, and the Newfoundland Medical Association.

The President (Sir Hugh Lett) said that in South Africa the reactions to the proposal for a British Commonwealth Medical Council had been enthusiastic. The Minister of Health in South Africa had shown great interest in the subject. People in the Transvaal as well as in the Cape warmly welcomed the idea; they had hitherto felt isolated; they very seldom saw anyone from Australia and never from Canada. In the

Transvaal the hope was expressed that it would be possible to combine the inaugural meeting with a scientific meeting. Some very good work was going on in South Africa, and there was much to be learned from the people there. It was an extraordinarily fine thing that during the last eighteen months, notwithstanding its great preoccupations, it had been possible for the Council to sponsor two such movements as the Empire Medical Advisory Bureau and the British Commonwealth Medical Council, both of which, he thought, would lead to very valuable results.

Promotions

The Council, on the recommendation of the Staffing Committee, promoted Drs. A. Macrae and D. P. Stevenson to be Deputy Secretaries of the Association as from April 1, 1948. It further resolved that the Scottish Secretary enjoy the status of a Deputy Secretary of the Association.

Other Business

The Council approved a Humble Address to be presented to the King and Queen on the occasion of their Silver Wedding.

Consideration was given to a suggestion by the Office Committee that the payment of a registration fee should be required of members attending Annual Meetings of the Association. Dr. Dain said that the former system of a guarantee by members of the Association in the locality of the Annual Meeting was somewhat outmoded. A great burden of work in any case fell upon the hosts, and it was not reasonable to require them to pay or guarantee the expense of the meeting in addition. After a short discussion the Council agreed that, as an experiment for one year, a registration fee of one guinea should be charged to members attending the Annual Meeting, but that members of the Representative Body should be exempted from this charge.

It was agreed that the title of the Dominions Committee should be altered to "The Colonies and Dependencies Committee." This followed from the proposal to establish a British Commonwealth Medical Council, which will deal more particularly with the development of co-operation with the Dominions.

The Council agreed to recommend to the Colonial Secretary the name of Col. A. H. Proctor as one eminently suitable to serve on the Colonial Advisory Medical Committee. The Secretary of State had asked the Association to submit names for consideration by him when making future appointments to that body.

On the proposal of the Armed Forces Committee it was agreed to recommend to the Representative Body the names of Major-General Sir Percy S. Tomlinson and Air Commodore J. Kyle as R.A.M.C. and R.A.F.M.S. representatives on the Council for a term of three years.

A report was submitted by the Film Committee, and the Council gave authority for the purchase of a sound projector and of suitable films for copying and placing in the Film Library on the understanding that a certain expenditure would not be exceeded.

The Council unanimously and with acclamation agreed to recommend to the Representative Body that Dr. Peter Macdonald, of York, and Prof. R. M. F. Picken, of Cardiff, be elected Vice-Presidents of the Association.

The late Service member returns in the plebiscite were announced. These were received from Service members after the closing date, and showed: Approvals 30, disapprovals 239.

It was intimated that Dr. J. H. Bruce, an Assistant Secretary, was resigning his position in view of his desire to take up general practice. The Council appointed Dr. E. Grey Turner, the son of Prof. G. Grey Turner, as an Assistant Secretary of the Association.

A report by the Committee on Nursing, embodying a memorandum on the recruitment and training of nurses to be submitted to the Ministry of Health by the Association in conjunction with such of the other independent bodies represented on the committee as might be willing to join, was presented to the Council by Dr. Mary Esslemont, and was approved. The Chairman congratulated Dr. Esslemont and her Committee on a constructive contribution to the nursing problem.

Other reports dealing with routine matters were from the Committee on Psychiatry and the Law (Dr. Thwaites), the

Journal Committee (Dr. Carter), the Hospitals Committee (Mr. Newell), and the Consultants and Specialists Committee (Mr. Moore).

Messrs. Hempsons were reappointed solicitors to the Association.

The final business of the Council was to approve the draft Annual Report, subject to adjustment in accordance with the decisions of the meeting, and the Council rose at 6.15 p.m.

THE NORTHERN IRELAND HEALTH SERVICE

BY

N. S. DICKSON, M.B.

AND

H. I. MCCLURE, F.R.C.S.Ed.

The main responsibility for the administration of the Service is vested in two bodies: (1) the General Health Services Board and (2) the Hospitals Authority. These bodies have delegated to them by the Minister the responsibility for the organization and day-to-day administration of the respective sections of the Service. They will perform these functions within regulations to be framed in consultation with the profession and various other interests. In addition provision is made for linking up the county and county borough health authorities with the activities of these two boards and for the performance by these health authorities of certain specific functions in relation to maternity and child welfare, health visiting, etc. Tuberculosis services are administered separately by the Northern Ireland Tuberculosis Authority in co-ordination with the Hospitals Authority.

General Health Services Board

The services covered by this Board include those of the family doctor, dentist, and chemist.

All members are appointed by the Minister of Health after consultation with the interest concerned. The Board will consist of a chairman, vice-chairman, and 16 to 24 other members. Doctors, dentists, and chemists will constitute one-half of the Board, the other half being laymen. The medical members will be general practitioners in active practice, and they will have not less than one-half of the places allocated to professional members. There will in addition be one or more persons representative of the hospitals authority.

The Board has full responsibility for the appointment of its staff—i.e., as to numbers, qualifications, and remuneration—subject to certain prescribed exceptions.

Functions

The functions of the Board are as follows:

- Responsibility for the day-to-day administration, including preparation and maintenance of lists of general practitioners undertaking to provide general medical services and maternity services.
- Establishment, equipment, and maintenance of health centres in such areas they think necessary (subject to approval of the Ministry of Health), at which the following facilities may be provided: (1) general medical services; (2) general dental services; (3) specialists and other out-patient services; (4) services required or authorized to be provided by health authorities, and educational authorities in relation to clinics and dispensaries.
- Provision of courses of instruction for persons providing any services under General Medical Services part of the Act or arrangements with universities, medical and dental schools, etc., for such courses.
- Provision of information and instruction and advice on matters relating to health and disease.

Provisions of Act for General Health Services

1. The right of every doctor resident in Northern Ireland to be included in the Service if he so wishes. It also entitles him to practise privately as well as taking part in the Service or to remain outside the Service and conduct private practice solely.

2. Freedom to practise in the place of his choice.

3. The doctor's contract to provide personal medical services will be with the General Health Services Board.

- The right of every general practitioner to be included on panel of general practitioners providing maternity services of general practitioners undertaking to provide medical assistance for midwives, if so requested by the midwife.
- A separate contract with the Board for the provision of maternity services with payment of a separate fee for each case.
- Remuneration to be entirely by capitation fee for each person on a doctor's list.
- Right of every person to choose his medical practitioner in accordance with the prescribed procedure.
- Special remuneration for doctors in special areas—i.e., densely populated.
- The capitation fee to be the same as in Britain.
- Right of appeal to the High Court from any decision of Tribunal relating to any person included in any list prescribed under the Act.
- Compensation for the loss of goodwill consequent on abolition of the sale of practices. This compensation to be on a parity with that of doctors in Britain, with provision for settlement by arbitration in the case of any dispute.
- Buying and selling of practices in Northern Ireland is provisionally abolished in agreement with the profession in N.I.
- The right of ownership be restored in Great Britain.
- N.I. Act will be amended to bring it into line with Great Britain. Further, no restrictions are included relating to the sale of doctors' houses or to existing partnership agreements.
- Interest at the rate of 2½% per annum will be paid annually from the appointed day until the time when compensation is paid.
- The transfer of dispensary property and compensation for dispensary medical officers for loss of office.
- Freedom of speech and publication.

Health Authority Provisions

- 1. (a) Arrangements for care, including dental, of expectant and nursing mothers and children not of school age. (b) Provision for services of general practitioners and midwives in patients' homes (if so requested) before, during, and after childbirth. (c) Health visitors. (d) Domestic help. (e) Arrangements with general practitioners for vaccination and immunization in area of each health authority.
- 2. In order to secure provision of these services the health authority may make arrangements with the Board, authority, any body or persons whose object is the provision of these services, and in addition a health authority may make provision for giving opportunity to: (a) any general practitioner providing general medical services to provide medical treatment and supervision; (b) any dentist providing general dental service to provide dental treatment and supervision; (c) any chemist to provide drugs, medicines, etc., for the purpose of functions of the health authority, including provision by doctors and dentists of part-time services at clinics or health centres, or, if needed, in the patient's home, or at the doctors' dentists' surgeries.

Dental Services

- The Board has a duty to make arrangements with dental practitioners for the provision of general dental treatment and appliances (subject to regulations). The provisions include:
 - Right of every dental practitioner resident in Northern Ireland to be included in the list of those providing general dental services;
 - (b) right of every person to choose his dental practitioner in accordance with the prescribed procedure.

Pharmaceutical Services

- No arrangement may be made by the Board with doctors or dentists (a) to provide pharmaceutical services to persons whom they are rendering general medical or dental services with certain prescribed exceptions; (b) for dispensing medicines except by chemists.

Hospital and Specialist Services

- The main principle underlying the hospital and specialist services part of the Act is that there will not be State ownership of the hospitals of Northern Ireland, but a unification of hospital service under the guidance and control of a voluntary

tary body, the Northern Ireland Hospitals Authority. While the hospitals and equipment will be vested in this body, the management of each hospital will remain very much as at present—that is to say, there will be at least a majority of the present personnel of the existing Committees of Management on each future Management Committee. The funds and endowments of each hospital will remain with each Management Committee to be used at the discretion of the Committee to supplement the essential maintenance of the hospital, which will be defrayed out of funds voted by Parliament on the recommendation of the Hospitals Authority and with the approval of the Ministries of Health and Local Government and Finance. All funds and endowments at present owned, or in future received, by each Hospital Management Committee will not be interfered with by the Hospitals Authority or the State, but will be used to supply amenities, including non-essential equipment and apparatus.

The Hospitals Authority will consist of those having practical experience in the management of hospitals, and will comprise persons nominated for appointment by the Minister of Health and Local Government, by the Queen's University of Belfast, and by organizations recognized by the Minister of Health as representative of the medical profession, and in particular of those members of that profession who are specialists, the Northern Ireland General Health Services Board, and representatives of the dental, nursing, and pharmaceutical professions, together with a person or persons appointed after consultation with the Northern Ireland Tuberculosis Authority. It will thus be seen that the Minister looks to those already experienced in hospital work, notably the present Management Committees and the medical staff, for the unification of the new hospital service. Not less than one-third of the members of the Authority shall be medical practitioners.

The first duty of the Authority will be to prepare in consultation with the Ministry of Health a scheme for a comprehensive hospital and specialist service, including, in collaboration with the Queen's University, Belfast, schemes for clinical medical and dental teaching and medical and dental research. Each Hospital Management Committee will be appointed by the Hospitals Authority after consultation with the various interests concerned, and will include representatives of the local health authority, the General Health Services Board, the medical and dental staff of the hospital, and the various voluntary organizations associated with the hospital. The chairman and vice-chairman will be elected by the members of the committee. It will be seen that the policy of the Government is being observed by "the maximum assistance with the minimum interference."

Each Management Committee will submit to the Hospitals Authority a scheme for its own administration and development, including provision for paying patients' beds and assisted-payment beds. Authority is contained in the Act for members of the medical staff to treat their own paying patients in hospital. Further provision is made for the retention of existing pay-beds and the addition of the pay-beds in the future. The Hospitals Authority may for the purpose of economy and efficiency extend existing hospitals, build new hospitals where required, and close down redundant or ineffective hospitals. The important keynote of the hospital services is the retention of its voluntary characteristics, for throughout the whole scheme the Minister relies on the continuance of the voluntary effort, particularly in regard to social medicine.

The Consultants and Specialists Group of the B.M.A., Northern Ireland, appreciate the action of the Minister in providing that appointments under the Hospitals Authority should be made through the assistance of an advisory appointments panel.

The great advantage of the comprehensive hospital services scheme as provided for in the Act is that it ensures for the hospital security from financial anxiety and the opportunities of development on sound lines with the assistance of those experienced in hospital administration and with the minimum of State interference. All this has been accomplished, notwithstanding over 400 amendments set down for the Committee stage of the Bill, by common sense, good will, and the mutual desire on the part of the Minister, the Rt. Hon. William Grant, his officials, the medical representatives, and all those other bodies intimately connected with health services in general to

produce for the benefit of the community the best possible comprehensive health service.

The B.M.A. Northern Ireland Branch have acknowledged their appreciation of the courtesy and help in negotiation and discussion extended by the Minister of Health and Local Government and his senior officials and appreciate their continued readiness to work in the closest collaboration for the future success of the Health Services Act (Northern Ireland).

The B.M.A. Northern Ireland Branch must also acknowledge the yeoman service rendered in the Committee stage of the Bill of the following Members of Parliament: Dr. G. Dougan, Mr. Howard Stevenson, Mr. Herbert Quin, and Lieut.-Col. A. R. Gordon.

In conclusion it may be helpful to set out the differences between the English and Northern Ireland Acts.

	England	N. Ireland.
Remuneration by capitation without basic salary	Not conceded	Conceded
Appeal to the courts	" "	"
Right of every registered general practitioner to be included in the Service	" "	"
Freedom to practise in the place of his choice	" "	"
Retention of ownership of practices	" "	Provisionally abolished
Removal of restrictive clause dealing with sale of doctors' houses; partnership, and assistantships	" "	Conceded
Retention by individual Hospital Management Committees of all endowments held by any hospital	" "	"
Permissive power to make regulations concerning remuneration, qualifications, and terms of service of any officer employed by any body under the Act	Conceded	Not conceded

HEARD AT HEADQUARTERS

Unwieldy

Something will have to be done about the size of the Representative Body. It has more than doubled itself in 25 years. At the Special Representative Meeting 384 representatives were present, or were entitled to be present, from home Divisions, and to these must be added on an ordinary occasion some 68 more from overseas. The increase, of course, is due to the remarkable growth of the Association and to the operation of the by-law which provides that every constituency of not less than 150 members is entitled to elect one additional representative for each complete 100 members in excess of 50. This enables some constituencies to bring along almost a cup-tie team to Tavistock Square. The accommodation in the Great Hall was severely taxed on the occasion of the S.R.M., when some representatives had to sit in the gallery. The Organization Committee is contemplating a scheme which would reduce the number of representatives to some 300, at which it stood before the war.

Fearsome Agenda

Also in need of attention is some drastic change in the agenda of the Representative Body. There is an Agenda Committee, but its function is limited to recommending the precedence of certain subjects. As matters stand every resolution coming from a Division is regarded as sacrosanct even though a dozen similar resolutions are on the agenda, and if the resolution is not moved the representative is given the right to speak to the one which is taken in its stead. This not merely prolongs the proceedings, but tends to stereotype them. It is difficult to suggest what can be done about it other than a self-denying ordinance by representatives themselves. Some political and trade union organizations have a committee in almost continuous session during their conferences dissecting the agenda and framing composite resolutions which sometimes short-circuit whole pages of motions.

Big Figures

The financial statement for 1947 which was submitted to the Council last week illustrated again the great strength of the Association. The subscriptions are up by £15,000. The *Journal* shows a handsome balance of nearly £28,000, more

than twice as much as the year before. On the other hand expenses increase steeply. The Association is one of the greatest patrons of the railways in this kingdom, and the £1,500 out of the Association's pocket for central meetings.

Co-operation with Dentists

One resolution before the recent Representative Meeting called for liaison with the British Dental Association, which is conducting its own fight over the National Health Service in its present form. Its Representative Board has recommended members not to accept service unless there are amendments. We believe that fields in which the two Associations could fully co-operate are being explored. One of them is obviously public relations, and another the interchange of information regarding any discussions with the Government. The British Dental Association represents about 60% of the members of the dental profession.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar.
Non-County Borough Councils.—Dartford, Radcliffe (limited to future appointments), Tottenham, Wallsend.

Urban District Councils.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Portslade, Redditch (restricted to new appointments), Tyldesley.

Scottish Burghs.—Motherwell and Wishaw.

RETURN TO PRACTICE

The Central Medical War Committee announces that Mr. Stuart Feggetter, M.S., F.R.C.S., has resumed civilian practice at 1 Brandling Park, Newcastle-upon-Tyne.

Association Notices

Diary of Central Meetings

APRIL

8 Thurs. Publishing Subcommittee, 11 a.m.

15 Thurs. Journal Committee, 2 p.m.

Branch and Division Meetings to be Held

NORTH OF ENGLAND BRANCH.—At Royal Victoria Infirmary, Newcastle-upon-Tyne, Thursday, April 8, 8.15 p.m. "A. Questions?" Question Master: Prof. E. Farquhar Murray. Speakers: Prof. R. V. Bradlaw, Mr. C. Gordon Irwin, Prof. J. Kennedy, Mr. F. McGuckin, Drs. Gavin Muir, J. B. Tilley, and H. F. Wattsford.

STOCKTON DIVISION.—At Stockton and Thornaby Hospital, Bostfield Lane, Stockton-on-Tees, Monday, April 5, 8.30 p.m. Clinical meeting.

Meetings of Branches and Divisions

MORPETH DIVISION

A meeting of the Morpeth Division was held on March 1. The chairman, Dr. Spence, introduced Mr. W. Grant Waugh and invited him to address the meeting.

Mr. Waugh began by showing a talking film in which he demonstrated and described the treatment of arthritis by the acidification of joints. Dr. Cowan, who works with Mr. Waugh at Sunderland Infirmary, described other methods of treatment used either instead of or to supplement the acid injections. Mr. Waugh then showed another film, which had been made at the Royal Free Hospital illustrating various modern aids for cripples.

Dr. Noble proposed a vote of thanks to Mr. Grant Waugh and Dr. Cowan, and this was cordially given.

The following have been appointed chairmen of Hospital Management Committees for certain hospital groups within the S.E. Metropolitan region: Camberwell: Mr. Harold Gibbons; Bermondsey and Southwark: Prof. T. B. Johnston; Greenwich and Deptford: Mr. E. C. Sherwood; Lewisham: Mr. Walter R. Owen; Woolwich: Alderman S. C. C. Harris; Sidcup and Swanley: Dr. Charles F. Brook; Dartford: Mr. W. L. Parry; Gravesend and Medway: Alderman R. W. Rule; North-east Kent: Alderman the Rev. Harcourt Samuel; Tunbridge Wells: Alderman R. H. Burrell; Orpington and Sevenoaks: Mr. Henry J. Lester; Bromley and Farnborough: Mr. Arthur Collins; Hastings: Councillor Mrs. A. Farnfield; Eastbourne: Mr. G. F. Bowes; Brighton and Loughborough: Mr. J. C. Gaukroger; Seamen's: Mr. F. A. Baker.

CHEMOTHERAPY OF CHOLERA WITH A NEW SULPHONAMIDE COMPOUND ("6257")

LABORATORY INVESTIGATIONS AND FIELD TRIALS

BY

S. S. BHATNAGAR, M.D., Ph.D., F.R.C.P.

Lieut.-Colonel, I.M.S. (Ret.)

J. de SA, B.Sc.

F. FERNANDES, M.Sc.

AND

P. V. DIVEKAR, B.Sc.

(From the Microbiological Department, St. Xavier's College, Bombay)

For a number of years Rogers's hypertonic saline and palliative drug therapy has formed the sheet anchor for the treatment of cholera. Recently sulphaguanidine has been aligned to it, particularly through the efforts of workers in Bengal, and has given encouraging results (Chopra *et al.*, 1941; Carruthers, 1942; Misra, 1944; Huang, 1944; Lahiri, 1945; Seal, 1946, 1947; and others).

An observation by one of us (S.S.B.) since 1939, that hexamethylenetetramine in a 10% solution in normal saline killed cholera vibrio in less than half an hour up to a concentration of 1 in 10^{12} , resulted in the production of a few compounds of hexamine linkage to sulphanilamide experiments with which on animal and human cholera infection, though interrupted by conditions of field service, gave hope of successful chemotherapy against this disease. From a chance discussion with the scientific department of Ciba (Basle) it transpired that their investigators (Meier, 1946; Druey, 1948), after studying a large series of sulpha derivatives of low solubility, had condensed a product—"6257"—of two molecules of sulphathiazole ("cibazol") and three molecules of formaldehyde with the formula $C_{21}H_{22}O_6N_6S_3$, the molecular configuration not having yet been worked out. The present study relates to *in vitro* and *in vivo* experiments with this compound against the cholera vibrio and to field trials on human cholera infection.

Laboratory Investigations

Culture.—The Inaba and Ogawa strains of *Vibrio cholerae*, grown on meat-infusion alkaline "baeto" agar (pH 8) at 37° C. for 18 to 24 hours, provided the test inocula for all the experiments. After suitable dilution with normal saline the initial bacterial concentration was estimated by opacity and controlled by pour-plate counts.

Drug Concentration.—The compound "6257" being only slightly soluble in water, it was suspended by means of 2% gum arabic in distilled water. A 20% drug suspension—the "standard drug suspension" of the text—was initially prepared and sterilized at 100° C. for 10 minutes only, this exposure being sufficient for the purpose. This suspension was suitably diluted as required.

Test Mixtures.—All *in vitro* experiments were carried out in 10 ml. of "disco baeto" peptone water (pH 8) to which was added the requisite amount of the drug and the required

number of bacterial cells, each suspended in 0.1 ml. volume. Peptone water not only is an excellent medium for the growth of the cholera vibrio, but its use also eliminates the possibility of erroneous results due to acid fermentation of the carbohydrate likely to be found in a meat-infusion substrate. The test mixtures and the control tubes were incubated at 37° C. ($\pm 0.5^\circ$ C.). It was not found necessary to raise the temperature of incubation any higher to witness bactericidal and growth-inhibiting activity, as has been the experience with other sulpha derivatives (White, 1939). At various periods after incubation (6, 12, and 24 hours) a measured amount of the fluid was withdrawn and serially diluted to seed alkaline agar plates for the purpose of counting the number of viable organisms.

Animal Experiments.—Adult mice of uniform stock 20–25 g. in weight, were employed in groups of 20 as an experimental unit, the controls being one-half this number. The Inaba strain was mouse-passaged till the cholera vibrio attained a virulence resulting in 100% deaths of untreated mice with a dose of 2,000 million organisms administered intraperitoneally. Twice this number (4,000 millions) was the test dose in the experiments reported here. Higher multiples of M.L.D. were given up after a few preliminary experiments on account of the danger of mortality from toxic action alone. The test dose consisted of organism freshly isolated from the intraperitoneal fluid of dead mice and grown only once on alkaline agar, since the cholera vibrio loses its virulence quickly when subcultured frequently.

In relation to the time of infection, the drug therapy was divided into (i) a pre-infective period of 48 hours and (ii) a post-infective period of 96 hours. The dosage is indicated in Table II. Oral feeding was carried out directly into the stomach of the animal with a special curved bulb-ended needle and syringe. This procedure was found to be simpler and more accurate than the drug-die intake method. No local irritation was observed after subcutaneous therapy.

Determinations of the blood concentration of the drug were carried out on non-infected animals given identical dosage, since frequent handling and bleeding of infected mice produced inconsistent results. The methods employed were those advocated by Bratton and Marshall (1939) and Churg and Lehr (1941).

In vitro Activity of "6257"

Serial dilutions of the sterile "standard drug suspension" were titrated against inocula of different size. The results of one of these experiments are reproduced in Table I.

TABLE I.—In vitro Activity of "6257" on the Inaba Strain of *Vibrio cholerae*: Bactericidal and Bacteriostatic Action

Dilution of 20% Standard Drug Suspension	Total Concentration of Drug (mg.)	Inoculum: Total No. of Bacterial Cells	Growth at 37° C. Colony Counts Hours after Incubation		
			6	12	24
Control	0	1×10^6	C	C	C
1: 50	200.00	"	—	—	—
1: 100	100.00	"	—	—	—
1: 200	50.00	"	4×10^4	4×10^4	—
1: 300	33.33	"	9×10^5	1.5×10^6	—
1: 400	25.00	"	6.5×10^6	18×10^6	9×10^5
1: 500	20.00	"	8×10^6	—	26×10^6
1: 600	16.66	"	C	C	34×10^6
1: 700	14.28	"	C	C	44×10^6
1: 800	12.50	"	C	C	60×10^6
1: 1,000	10.00	"	C	C	C
1: 2,000	5.00	"	C	C	C

C Indicates confluent growth. — Indicates no growth. Columns 4, 5, and 6 show the total number of viable organisms in the test mixture.

The Table shows that a marked bactericidal and inhibitory activity is exercised by "6257" on the Inaba strain of *Vibrio cholerae*. Similar results were obtained with the Ogawa strain.

When an inoculum of one million cholera vibrios was incubated with 200, 100, 50, and 33.3 mg. of the compound for 24 hours, samples plated on alkaline agar remained sterile. Further confirmation of this finding was obtained by subjecting the total volume of 10.2 ml. of the test mixtures to two other viability tests—namely, fractional division over 10 plates by the pour-plate method, when there was complete absence of colonies after 48 hours' incubation, and fractional transfer into 100 tubes of glucose-peptone water, with Andrade's indicator. In the latter test the absence of turbidity and acid fermentation, after similar incubation, was taken as an index of non-viability.

Two other possible pitfalls in these tests were also excluded—namely, (a) there was no adverse effect of increase in hydrogen-ion concentration consequent on bacterial multiplication, since the pH values of the test mixtures were found not to exceed 8.6, and (b) there was no bactericidal activity of gum arabic *per se*.

It would appear that the drug has both bactericidal and bacteriostatic activity.

In vivo Activity of "6257"

The experiment recorded in Table II confirms the result of the *in vitro* tests. When the drug was administered by the

TABLE II.—In vivo Activity of "6257"

Route of Administration	Treatment						Test Dose Inoculated Intraperitoneally 4,000 million Organisms	No. of Mice Infected	Survivors	
	Daily Dosage in mg.								No.	%
	Before Infection No. of Days	After Infection No. of Days								
		1	2	3	4					
Intraperitoneal	50	40	40	40	40	40	2 M.L.D.	20	20	100
Subcutaneous	50	40	40	40	40	40	2 "	20	20	100
Oral	50	40	40	40	40	40	2 "	20	4	20
Controls	2 "	10	0	0
							2 " tive boiled culture	10	10	100

intraperitoneal and subcutaneous routes it exercised a powerful protective action on cholera-infected mice. With the oral method, however, it was not possible to save more than 20% of the animals.

Post-mortem examination revealed that intraperitoneal cholera infection was followed by invasion of the tissues

within a few hours, the infecting organism being isolated from heart-blood, liver, and spleen. Biochemical examination of the blood showed that the absorption of "6257" by the parenteral routes was slow, and still more so when given by mouth. The excretion of the drug being equally slow, a much flatter concentration curve in comparison with other sulphur derivatives was the result. Prior to infection, therefore, an effective blood level was initiated with 80–90 mg of the drug, and was maintained with a daily dosage of 40 mg. in the post-infective period for four days, in the belief that, *vis-à-vis* rapid mouse septicaemia, the therapeutic results could be conditioned only by the concentration of the drug in the blood and the tissues. That this assumption was correct was borne out by the results obtained—i.e., 100% protection by the intraperitoneal and subcutaneous routes and only 20% survival through oral therapy.

Field Trials

In all, 85 cases of cholera were treated in 27 villages in the "talukas" of Kumbhakonam, Tiruvarur, and Nega-patam of the Tanjore district, in the south-east of Madras Presidency, during November and December. Records for the past seven years show that the disease could be considered to be endemic in that area, and its highest incidence was from September to February, with a case mortality in the region of 60%. The patients were treated in their homes without the benefit of nursing and general medical care, and no complementary treatment in the form of saline and palliative drug therapy was resorted to.

Bacteriological Diagnosis.—In all the cases the diagnosis was established by the following procedure, minor details being omitted.

A capillary-pipette drop of a saline suspension of the stool, standardized by opacity, was transferred to Dunham's peptone water (pH 8) and incubated at 37° C. The pellicle from the growth developing in 8 to 24 hours was plated on to MacConkey's agar. This medium offered the advantage that the non-lactose-fermenting cholera vibrio could be easily differentiated from lactose fermenters for the purpose of quantitative studies, referred to later. After morphological examination five to six suspected colonies were transferred on to an alkaline agar slope and the growth tested against a mixed Inaba-Ogawa agglutinating rabbit serum (titre 1 in 5,000).

Classification of Cases.—The typical symptoms of cholera—purgation, rice-water stools, vomiting, dehydration, anuria, algidity, cramps, imperceptible pulse, and an apathetic-to-comatose mental state—were encountered in different combinations. The clinical picture could be differentiated into three stages of infection according to severity and, what was important from our point of view, to the period at which the treatment was started: (1) The primary

stage, in which purgation was the main feature with little or no vomiting and no prostration—the "moderately severe" cases. It was difficult to contact these patients because the difficulties of transport caused delay in notification. (2) The secondary stage, characterized by passage of rice-water stools, frequent vomiting, and

prostration but no anuria—referred to as "severe" cases.

3) The critical stage, of which anuria and dehydration were the marked features, with a semi-comatose condition, rigidity, imperceptible pulse, and body cramps. The term "serious" is here applied to these cases.

Table III summarizes some of the salient features of the cases treated during the course of a cholera outbreak in an endemic area. The great majority of the patients belonged to the "untouchable" labouring class, many of

in the course of two to three hours. In six cases where this practice did not succeed, on account of hyperemesis and a comatose condition, the drug was given per rectum in a 6-g. dose suspended in gum arabic in 50 ml. volume, high up the colon, by the employment of a long piece of rubber tubing. The beneficial effect of this measure made it possible to proceed with the second dose orally.

The earlier cases were given the drug more frequently, in smaller doses. Experience, however, showed that to get

TABLE III.—Analysis of Treated Cholera Cases

Clinical Course	No. Treated	No. Surviving	Sex		Age Groups (Years)								Inoculated		Uninoculated
			Male	Female	5-10	10-20	20-30	30-40	40-50	50-60	60-70	70-80	No. Attacked	No. Attacked in Negative Phase	
Moderately severe cases (primary stage)	12	12	4	8	2	7	2	1	—	—	—	—	2	—	10
Severe cases (secondary stage)	16	16	7	9	3	2	5	4	1	1	—	—	3	—	13

Total	85	82	35	50	15	17	22	14	12	3	1	1	16	11	69

them women and children, with one feature common to all—malnutrition. The outbreak was characterized as severe by the local health authorities. This was borne out by the galloping march of symptoms, the patient being dangerously ill six to eight hours after the initial clinical manifestations, with dehydration and all its sequelae.

The scarcity of the drug precluded us from treating more than 85 cases: the total quantity available for the trial was 3,800 g. in the form of powder and in tablets of 0.5 g.

Treatment and Results

The average amount given was 16 g. for a child, 3 g. for an adult female, and 25–30 g. for an adult male, according to the scheme shown in Table IV.

TABLE IV.—Dosage of "6257" for Oral Treatment of Cholera Patients

Day of Treatment	Daily Dosage (Grammes)		
	Children	Women	Men
1st	6	10	10
2nd	4	4	4
3rd	2	4	4
4th	1	2	2
5th	1	1	1
6th	1	1	1
7th	1	1	1

The subcutaneous route was first tried in view of the results of the experiments in mice. It soon became clear, however, that parenteral therapy did not bring about any clinical amelioration. Obviously the treatment of cholera septicaemia in the mouse could not serve as a guide to the treatment of human disease, which in the bacteriological sense is confined to the intestinal tract alone.

Oral therapy was therefore practised and it immediately gave gratifying results. The pleasant observation also was made that "6257," in sharp contrast to other sulphamide derivatives, including sulphaguanidine, had no appreciable toxic effects. As much as 50 g. was administered to some of the cases without causing or accentuating nausea or vomiting. On a few occasions when blood was examined for agranulocytosis the findings were negative. Four women in advanced stages of pregnancy were treated successfully without any ill effects.

The retention of the drug in the presence of frequent vomiting was achieved by substituting 0.5-g. tablets in place of the powder, two tablets being given fractionally every 10 to 15 minutes until the full dose of 6 g. was ingested

the best and quickest results it was essential to start with a large dose of 6 g. and to follow it with another large dose of 4 g. four hours later, and then to watch carefully the progress of the case. Six to eight hours after starting treatment purgation diminished and vomiting stopped. By the ninth hour, as a rule, the patient had passed water, although in three seriously ill cases it took as long as 20 to 24 hours. Nourishment in the form of barley or rice "kunji" (decoction) greatly helped to restore the kidney function.

There was distinct improvement by the end of 24 hours. Purgation was much reduced and nausea, vomiting, and cramps were absent. Although the patient was weak and dehydrated, the pulse was perceptible and interest was taken in the surroundings. By the 48th hour the body was warm and dehydration reduced in proportion to fluid intake, which was insisted upon. By the morning of the fourth day the patient was convalescent and well on the way to recovery. As an illustration, the case histories of two patients—one treated orally and the other per rectum, with subsequent oral therapy—are here given.

Illustrative Cases

Case 27.—A man aged 40, uninoculated. Symptoms started at 3 a.m.; visited 12.45 p.m.; patient in critical stage: 5 motions; 7 vomits; dehydrated; comatose; anuria; cramps; pulse imperceptible, body cold. Treatment was as follows:—Dec. 3: 1 p.m., 6 g. powder, all vomited; 1.40 p.m., 6 g. tablets retained; 8 p.m., 4 g. tablets retained. Dec. 4: 8 a.m., 2 liquid motions during night; anuria persisted; 4 g. tablets retained; 1 p.m., urine passed; no vomit; one liquid motion; dehydrated; apathetic. Dec. 5: 9.30 a.m., sitting up; pulse perceptible; one motion during night; still dehydrated and weak; 2 g. powder retained; 5 p.m., cheerful; answers questions; fluids taken; dehydration less; 2 g. powder retained. Dec. 6: 8 a.m., solid motion; free urine; body warm; rapid low-volume pulse; 1 g. powder; 6 p.m., 1 g. tablets. Dec. 7, 8, 9, 10: 0.5 g. tablets morning and evening; patient recovered.

Case 11.—A man aged 29, inoculated Nov. 23; symptoms Nov. 25, 10 a.m.; visited 6 p.m.; 10 motions; vomiting started 2 p.m.; no urine since 4 p.m.; body cold; pulse imperceptible; semi-comatose. Treatment was as follows:—Nov. 25: 6 p.m., powder by mouth not retained; tablets also brought up as vomit every 10 minutes. 9 p.m., 6 g. drug per rectum, most of it retained. 12 p.m., 4 g. tablets fractionally; about 2 g. retained. Nov. 26: 8 a.m., 4 rice-water motions during the night; nausea but no vomiting; body cold; pulse imperceptible; 6 g. tablets fractionally retained; 4 p.m., 2 motions; free flow of urine; dehydrated; semi-comatose; 4 g. powder retained. Nov. 27: 9 a.m., 2 motions; free urine; dehydrated; free

pulse; cold; 4 g. powder; 5 p.m., no motion; no vomiting; cheerful but weak; 2 g. powder. Nov. 28: 8 a.m., much better; semi-solid motion; body warm; pulse perceptible; dehydration much less; 2 g. powder. Nov. 28, 29, 30: 0.5 g. tablet morning and evening; patient recovered.

Mortality

Table III shows that all the cases in the primary and secondary stages of infection recovered, but three out of 57 cases in the critical stage could not be saved. In two of them the symptoms developed during the negative phase, within 12 hours after the inoculation of cholera vaccine, and were serious in character.

The first fatal case was that of a female, 25 years of age, who was visited 8 hours after the onset and responded well to 14 g. of the drug. Next morning, however, she was found by her neighbours in a state of collapse on the river bank, where she had gone to fetch water. She survived only two hours thereafter.

The second case was that of a man aged 63 with a long history of chronic diarrhoea who passed blood-stained stools in spite of treatment. He died within 10 hours as a result of anuria.

The third patient, a man aged 35, was visited within six hours of onset and given 11 g. of the drug in the next eight hours, the evening report being no motion and no vomit, but anuria persisting. The sanitary inspector, however, reported next morning that the patient had died in the middle of the night. A necropsy not being possible, it was presumed that he had succumbed to uraemia.

Epidemiological Significance of 7-day Therapy

As a rule, patients could be said to have recovered by the end of 72 hours; nevertheless, a schedule of treatment extending over seven days is advised. This recommendation is based on observations regarding the persistence of cholera vibrios in the stools of cases under treatment (for details see Fernandes, 1948). In the present series of cases the excreta could be said to be free from vibrios on the sixth day.

Another observation of epidemiological significance was the freedom of contacts from subsequent attacks of the disease though living in the restricted areas of cholera-infected hamlets. The seven-day drug therapy outlined in Table IV cannot therefore be too strongly recommended in the interest of the patient as well as that of the community.

Prophylactic Treatment in the Negative Phase following Cholera Vaccination

A matter that has not received sufficient consideration is the danger of possible precipitation of a serious attack of cholera from the common practice of protective inoculation of contacts, amongst whom may be persons who are harbouring the cholera vibrio or who may actually be in the incubation period of the disease. Similar experiences are known in the case of typhoid fever (Bhatnagar, Freeman, and Dhilon, 1937). Table III shows that of the 16 cases of cholera amongst the inoculated population as many as 11 were attacked in the negative phase, the infection being severe in all of them and responsible for two out of three deaths in this series.

In co-operation with the local health authorities, 4 g. of the drug, in two equal doses, was given morning and evening for two days immediately after inoculation to the contacts of treated cases in one of the villages. Although the figures are not sufficient for any conclusions to be drawn, the health authorities were struck by the freedom from infection of persons subjected to this simple therapy in comparison with those not so treated.

Discussion

The evidence presented here, in spite of its limitation in scope, clearly indicates the role of the compound "6257" in the treatment of cholera as well as in its prophylaxis. To deal with an epidemic effectively, the form of treatment at present practised necessitates the mobilization of a considerable amount of hospital accommodation, medical equipment, and personnel, all of which are limited in countries where the disease is endemic. In the absence of these amenities the results of our field trials emphasized the economic advantage of the method advocated. Consider-

ing the survival rate alone, our experiences compare very favourably with those of others obtained from the application of combined sulphaguanidine, saline, and palliative drug therapy.

Without minimizing the curative aspect of this treatment we attach very great importance to the complete freedom from cholera vibrios of the stools of treated cases—accomplished, as we have shown, by seven-day drug therapy. It was our experience that this simple measure brought about a very material reduction in the number of carriers, who, along with the prevailing insanitary conditions, are the backbone of any cholera epidemic, be it in an endemic area or following in the wake of big religious gatherings. If in addition the contacts of a case of cholera were protected by prophylactic treatment with the drug as indicated, particularly in the short negative phase after concomitant cholera inoculation, there is a possibility that this disease would cease to be a major problem of preventive medicine. Future trials on a more extensive scale will prove if the thesis advanced here is correct.

The preparation of "6257" by the molecular combination of two different chemical components is a departure from the common practice of obtaining sulpha derivatives by additions to, and the substitution of, the radicals of sulphanilamide. There are two references in the literature to attempts in the same direction—namely, the preparation of "septurit," a compound manufactured in the early days of sulphanilamide chemistry, and "strepturin" (Astra khantsev and Vasil'ev, 1940), found by Russian scientists to be effective against streptococcal infection.

The two outstanding properties of "6257" that are in sharp contrast to those of other sulpha derivatives are: (a) the absence of toxicity within the zone of therapeutic action, tested both in laboratory animals and in human beings; and (b) its slow absorption from a subcutaneous "depot" and equally slow excretion from the system, so that blood concentration can be maintained at a higher level for a longer period of time. The first of these properties would presumably be attributable to the formaldehyde radical, a well-known detoxicant of bacterial toxins, whereas the second would appear to be related to the high molecular weight of the compound.

The absence of both these attributes, particularly the former, was responsible for relegating the sulpha compounds to a position in clinical therapy secondary to that of the antibiotics. If future experience showed that the therapeutic value of "6257," and that of other similarly prepared compounds possessing these two qualities, extended over a wider field of pathogenetically important bacterial species, it might be that sulpha derivatives would through these new compounds regain their place of priority in clinical therapy—a welcome reversion from the point of view of production as well as of economy.

Summary

The new compound "6257"—a condensation product of sulphathiazole ("cibazol") and formaldehyde—shows *in vitro* a marked bactericidal and growth-inhibiting action against *Vibrio cholerae*.

When administered parenterally to mice, it offers 100% protection against septicaemia resulting from intraperitoneal cholera infection. When given by mouth it is, however, not so successful. The discrepancy is due to low blood-concentration value of the drug.

When patients suffering from cholera in an endemic area during the course of an epidemic were treated in their homes in villages with this drug alone, in the absence of nursing, general medical care, and any form of adjuvant treatment, the survival rate compared very favourably with that obtained by present-day recognized therapy.

In the control of an epidemic of cholera the importance of complete freedom from cholera vibrio of the stools of cases treated by seven-day drug therapy, and the prophylactic treatment of contacts with the drug, is emphasized.

The role of two properties of this drug—namely, the absence of toxic action and slow absorption and slow excretion—is discussed in its bearing on future sulpha therapy as opposed to antibiotics.

Our grateful thanks are due to Major-General S. L. Bhatia, Surgeon General to the Government of Madras, Drs. Mathews and Lal, Director and Assistant Director of Public Health, for their co-operation, and to Dr. R. Ramaswamy, District Health Officer, Madras, and his staff for their excellent help, which made this investigation possible.

TREATMENT OF RINGWORM OF THE SCALP

BY

REGINALD T. BRAIN

KENNETH CROW

H. HABER

C. McKENNY

AND

J. W. HADGRAFT, Ph.C., A.R.I.C.

From the St. John's Hospital for Diseases of the Skin and the Royal Free Hospital

Until recent years there was no reliable treatment of ringworm of the scalp which did not involve removal of infected hairs from their follicles by the use of x rays or thallium acetate or by producing a purulent folliculitis. The removal of infected hairs with masses of spores was in itself inadequate to effect a cure, but it so enhanced the effect of local treatment with fungicides that x-ray epilation became the accepted practice of dermatologists and reduced the duration of treatment from an indefinite number of years to one or two months. For example, a series of 30 cases of ringworm of the scalp were treated from Feb. 13 to Sept. 29, 1947, by Dr. McKenny, at St. John's Hospital for Diseases of the Skin, by x-ray epilation followed by the application of Whitfield's ointment and bi-weekly paintings with tincture of iodine. The x-ray technique was the irradiation of the usual five areas (Kienböck-damson) with a dose of approximately 400 r to each area at 90 kV, the half-value layer equivalent to 1.4 mm. of aluminium, and focal skin distance 9½ in. (24 cm.). The diameter of the active field being 5 in. (12.5 cm.). All the patients were examined by Wood's filtered ultra-violet light or microscopically, or both, to confirm the diagnosis and again about one month later, and then at intervals of two weeks until three examinations had been negative.

The average number of days for a cure was 38.4, but four cases required treatment for 85, 85, 151, and 160 days; thus the average period for cure in the other 96 was 35 days. These results are considered to be highly satisfactory, but they were obtained in a very well equipped and specialized clinic. Moreover, the x-ray technique is tedious and exacting and occupies at least an hour. Under such conditions the risk of any permanent alopecia is negligible and certainly much less than that of toxic reactions to thallium acetate, but the risks have to be borne in mind, and they have always brought anxiety to the doctor and to the parents of children under treatment.

It was therefore disappointing to find in our own experience and in that of Carrick (1946) and others that new and potent fungicides were no more effective in the treatment of scalp ringworm than the older remedies, and it was obvious that this must be due to their failure to penetrate the infected follicles. At first it was hoped to overcome this difficulty by using fat solvents such as acetone, benzene, carbon tetrachloride, chloroform, and alcohol containing iodine or benzoic and salicylic acids, but these met with little success.

The interesting fact that while microsporon infections of the scalp are common in children they are very rare in adults led to the discovery by Stephen Rothman and his co-workers (1946, 1947) that a certain fraction of the free fatty acids extracted from adult human hair was capable of inhibiting the growth of *Microsporon audouinii* in concentrations of 0.0002–0.0005%. Pelargonic acid was the main constituent of this fraction, but no success followed its therapeutic use, probably because of its lack of penetrating power.

Penetrating Vehicles

Attention was therefore directed to the use of penetrating vehicles which might carry an effective fungicide to the base of the hair follicle and make possible the cure of scalp ringworm by simple inunction or even by painting the scalp without preliminary epilation. In recent years this problem has received considerable attention in America. Herrmann, Sulzberger and Baer (1944) and MacKee, Sulzberger, Herrmann, and Baer (1945) have reported on the use of vehicles containing wetting agents to promote skin penetration. MacKee, Herrmann, and Karp (1946) found that the most promising results in the treatment of tinea capitis were obtained with a preparation containing cetyltrimethylammonium pentachlorophenate 3.5% in "intraderm." The latter consists of a combination of sodium alkylbenzene sulphonate 5%, phenazone 12.5%, propylene glycol 10%, sulphonated castor oil 10%, and distilled water. The pH was adjusted to 4 by the addition of citric and propionic acids. In addition to the application of the solution the treatment included the use of an acid shampoo containing sodium alkylbenzene sulphonate and sulphonated castor oil. In a series of 59 cases of infection with *M. audouinii*, 54% of the children were cured, the average duration of treatment being approximately 14 weeks. More recently Foley and Lee (1947) have reported on the fungicidal action of combinations of cetyltrimethylammonium pentachlorophenate with fatty acids. The combination found to be most active against pathogenic fungi was cetyltrimethylammonium pentachlorophenate and undecylenic acid.

Fungicidal Agents

In the preliminary experiments of our series phenylmercuric nitrate and salicylanilide have been used as the fungicidal agents. Phenylmercuric nitrate was investigated clinically in 1933 by Levine, who reported favourably on its use in aqueous ointment bases for the treatment of epidermophytosis and tinea. It possesses low toxicity, and

in addition to its fungicidal properties has marked bacteriostatic and bactericidal actions. Byrne (1947) reviewed its application to diseases of the skin.

An attempt was made to incorporate phenylmercuric nitrate into the intraderm vehicle of Herrmann *et al.*, using alkyl-naphthalene sulphonate in place of alkylbenzene sulphonate, since the latter substance was not available in this country. Phenylmercuric nitrate, however, was found to be incompatible with alkyl-naphthalene sulphonate and with other wetting agents containing the sulphonic group.

A search was made for alternative wetting agents compatible with phenylmercuric nitrate. The Crill series of wetting agents* are non-ionic in character and consist of long-chain fatty-acid derivatives of various carbohydrates, such as sorbitan and mannitan. The series comprises 30 members in all, and Crill No. 6 was chosen for the present purpose as it produces the greatest reduction of surface tension in the range. Crill No. 6 is an ethylene oxide derivative of sorbitan monolaurate and is a pale-straw-coloured viscous liquid having a faint odour reminiscent of linseed oil. It is miscible with water and with vegetable and mineral oils. The solubility of phenylmercuric nitrate in water is increased by the presence of Crill No. 6, with which it is compatible.

Various combinations of Crill No. 6, propylene glycol, and water were prepared, the pH being adjusted to between 4 and 5 by the addition of a solution of citric acid (2%) and sodium propionate (1%).

Solution No. 1

Phenylmercuric nitrate	1 g.
Crill No. 6	100 ml.
Propylene glycol	100 ml.
Solution of citric acid and sodium propionate	20 ml.
Distilled water	to 1,000 ml.

Dissolve the phenylmercuric nitrate in a mixture of Crill No. 6, propylene glycol, and 100 ml. of distilled water. Add the solution of citric acid and sodium propionate and adjust the volume by the addition of distilled water.

This solution deposited slightly on standing for 14 days, owing to the presence of propylene glycol. It was therefore decided to replace the propylene glycol by phenoxetol, the antibacterial properties of which have been reported by Berry *et al.* (1944) and which also has a powerful fungicidal action. Phenoxetol is only sparingly soluble in water, and therefore it was necessary to increase the concentration of Crill No. 6 in order to obtain complete miscibility. The concentration of phenylmercuric nitrate was also increased.

Solution No. 2

Phenylmercuric nitrate	2 g.
Phenoxetol	200 ml.
Crill No. 6	400 ml.
Solution of citric acid and sodium propionate	20 ml.
Distilled water	to 1,000 ml.

In order to obtain a preparation easier to apply, a cream was made according to the following formula:

Cream No. 1

Phenylmercuric nitrate	2 g.
Phenoxetol	200 ml.
Crill No. 6	200 ml.
Solution of citric acid and sodium propionate	20 ml.
Lanette wax SX	100 g.
Distilled water	to 1,000 ml.

Heat together, over a water-bath, the phenoxetol, Crill No. 6, and lanette wax SX until the latter is melted. Dissolve the phenylmercuric nitrate in the mixture. Add the solution of citric acid and sodium propionate to the distilled water, heat over a water-bath and add gradually with constant stirring to the mixture of lanette wax SX and other ingredients. Stir until cool.

*Marketed by Croda, Ltd., London.

The concentration of phenylmercuric nitrate was subsequently increased to 0.5%:

Cream No. 2

Phenylmercuric nitrate	5 g.
Phenoxetol	200 ml.
Crill No. 6	200 ml.
Solution of citric acid and sodium propionate	20 ml.
Lanette wax SX	100 g.
Distilled water	to 1,000 ml.

Another type of ointment base used in America consists of polyethylene glycol, the dermatological applications of which have been described by Hopkins (1946). This substance* is available in various grades, the lower members being liquids and the higher members having consistencies varying from that of soft paraffin to hard waxes. "Carbowax '1500'" is a member of the polyethylene glycol series and is similar in consistency and appearance to white soft paraffin. It is soluble in water but immiscible with mineral and vegetable oils and fats. Carbowax "1500" will itself dissolve many organic compounds, and by the addition of Crill No. 6 its solvent powers may be increased.

Phenylmercuric Nitrate

In these experiments the preparation giving the best results consists of phenylmercuric nitrate 0.5% in a base composed of carbowax "1500" and Crill No. 6, the pH being adjusted to between 4 and 5 by the addition of a solution of citric acid and sodium propionate. Unfortunately we have no experimental evidence of the penetrating properties of the carbowax compounds or of the effect of adding wetting agents to ointment bases of this type, but this is a matter which we have under investigation.

Ointment No. 1

Phenylmercuric nitrate	5 g.
Crill No. 6	100 ml.
Solution of citric acid and sodium propionate	20 ml.
Carbowax "1500"	to 1,000 g.

Melt together the carbowax "1500" and Crill No. 6 over a water-bath; add the phenylmercuric nitrate, previously triturated with the solution of citric acid and sodium propionate, and continue heating until the phenylmercuric nitrate is completely dissolved. Allow to cool.

Salicylanilide

Salicylanilide is another fungicide which has received attention in America; in this series it has been used in order to assess its value against that of phenylmercuric nitrate. Of 17 preparations tested by Schwartz (1946) the most efficacious was an ointment containing 5% salicylanilide and 5% hyamine in carbowax "1500." In the present series an ointment containing 5% salicylanilide in the carbowax "1500"-Crill No. 6 base is under investigation.

J. L. Miller *et al.* (1946) reviewed the use of various fungicides in special vehicles, including carbowax, using sodium tetradecyl sulphate as a wetting agent. Daily manual epilation of the diseased hairs was part of the technique.

Ointment No. 2

Salicylanilide	50 g.
Crill No. 6	100 ml.
Solution of citric acid and sodium propionate	20 ml.
Carbowax "1500"	to 1,000 g.

Heat together the carbowax "1500" and the Crill No. 6 over a water-bath, dissolve the salicylanilide in the mixture, and add the solution of citric acid and sodium propionate. Stir and allow to cool.

These preparations, as made and described by Mr Hadgraft, chief pharmacist to the Royal Free Hospital

*The "carbowax" compounds are marketed in this country by General Metallurgical and Chemical, Ltd.

be submitted to clinical trial, and the modifications were introduced in attempts to achieve more rapid progress. We far from being satisfied that the present ointments represent the goal we are seeking, for we think that too much depends upon an exacting technique of application. However, in spite of the observations of others to the contrary (MacKee, Herrmann, and Karp, 1946), we find that inflammatory reactions in the follicles, if not essential, are of value in accelerating cure. This has been generally accepted in the past with older methods, but it is hoped that with more powerful fungicides and bases of greater penetrative power it may soon be possible to treat non-inflammatory ringworm of the scalp without provoking reactions in the skin and its follicles.

Clinical Results

The following is the preliminary report on 22 cases of ringworm of the scalp treated with Ointment No. 1 at John's Hospital for Diseases of the Skin. There were boys, 8 girls, and 1 woman. All were treated as outpatients. Every patient was examined microscopically and tested under Wood's light, and the fungus was identified by culture. There were 8 cases of *M. audouinii*, 9 cases of *M. felineum*, 4 cases of microsporia, and 1 case of *Trichophyton endothrix* which could not be identified. The patients were given written and verbal instructions. The following routine was carried out:

The hair was cut short and kept short throughout the treatment; a linen cap was worn for 24 hours continuously; every morning the scalp was washed with soap and hot water and scrubbed with a nailbrush, particular attention being paid to the infected patches. The ointment was applied three times a day with a toothbrush for five minutes. It was thought that by using a fungicide of high potency and a penetrating base, combined with mechanical irritation caused at producing active hyperaemia and mechanical action, favourable results might be obtained. Phenylmercuric nitrate is a fungicide of high potency. Carbowaxes combine penetrating properties with pleasantness of application, thanks to its quality of mixing easily with water. The nailbrush, applied with gentle vigour to the affected areas, should help to dislodge the infected hair, which when caught by the coarse bristles should be easily removed from the follicles. This has proved to be correct. The toothbrush is a comfortable applicator, and the friction is its factor in producing irritation. We still consider it to be a useful preliminary measure in facilitating eradication within the follicles. X-ray epilation itself does

not cure ringworm of the scalp: treatment with fungicides must follow to complete the cure. Pustulation and kerion formation cause natural epilation. That is one reason why many cases of animal ringworm are easily cured by local applications alone. The inflammatory response, which occurs much more often in the animal than in the human type of ringworm, also plays an important part in natural cure. It is that entire lack of any local reaction which accounts for the difficulty of eradicating *M. audouinii* infection by local means only.

The clinical appearance of all cases at the beginning of treatment varied between slight scaliness and severe pustulation of the patches. Co-operation of the parents was the first condition of successful treatment. Some mothers refused to cut their children's hair and some were unwilling from the very start to treat their children, and preferred the established x-ray technique. The children reacted very well to treatment, the range of reaction being that of slight erythema and scaling to more or less severe pustulation. Details are given in the Table. Some cases did not show reaction at all and it was thought that painting with pure phenol once or twice would induce pustulation, but after attempting it in three or four cases it was abandoned as unnecessary. One case reacted too violently and the mother refused further treatment; incidentally, that case when seen several weeks later was negative to Wood's light. In one case the Kromayer lamp was employed several times, but without appreciable benefit.

Summarizing, the inflammatory action when already present was welcomed, and in cases where it was absent it was intentionally provoked. Patients were at first seen every week; but later, with mounting experience, they were asked to visit the clinic every three weeks. Improvement could usually be seen between the first and seventh weeks of treatment, this showing itself by thinning of the fluorescent patches and a change in the colour of the infected hair from bright green to white. In our experience when a case became negative it remained so, therefore after the first negative reaction to Wood's light the treatment was continued for only one week and was then stopped. After three negative fluorescent tests the patient was discharged.

It was not always possible to get every patient for three-monthly tests, so that a few cases were followed up for one month only. The Table gives a detailed account of the course of treatment of the 22 cases.

(a) Cases of *M. audouinii*.—There were 6 boys and 2 girls in this group. Six cases were cured and two failed. The

(T. end.)

A = *M. audouinii*. B = *M. felineum*

number of days of treatment of the cured cases was 330, the average time for each case being 55 days. Improvement began between the third and eighth weeks of treatment, and once the improvement started it took from two to four weeks for the cases to become negative. There was no relapse. The time of observation was from one to four months. Pustulation occurred in three cases, slight reaction in two, and no reaction in one. In Case 7 the nailbrush was not used. Cases 7 and 8, which failed, were cured by x rays in one and four months respectively. It is interesting to note that Case 8, which was treated locally for 120 days, took exactly the same time for cure after x-ray epilation. It was necessary to carry out several local manual epilations combined with antiseptics to effect a cure.

(b) *Cases of M. felinum*.—There were 6 boys, 2 girls, and 1 woman. Eight cases were cured and one failed. The average time of cure was 75 days, excluding Case 17. Improvement began between the first and sixth weeks of treatment. It took one to six weeks for the cases to become negative once the improvement started. The time of observation varied from one to four months. Case 11 showed severe pustulation and refused further treatment. When examined several weeks later this patient was found to be negative to Wood's light; we considered, therefore, that he was cured.

It is interesting to note that there was a difference of about three weeks in the time of cure between the human and the animal types of ringworm. Variation in the resistance of the individual fungus, and last, but not least, the co-operation of the mother, might be responsible for variations in therapeutic response. Case 17 (*M. felinum*) started treatment in November, 1946, and was discharged cured in September, 1947. It was impossible to persuade this patient to cut her hair, and the treatment, therefore, was technically very difficult. It was confined to the inunction of ointments into the affected area. Different kinds of ointments were used for a considerable time, but when Ointment No. 1, combined with mechanical epilation, was employed she was cured in six weeks.

(c) *Cases 18-21* could not be identified by culture. We cannot therefore make any further comment upon them, except that Cases 20 and 21 were cured by x-ray epilation in five and four weeks respectively.

(d) *Case 22*.—A 9-year-old girl had suffered from *T. endothrix* infection for seven months. Clinically she presented widespread inflamed patches over the scalp. The Wood's light test was negative. No identification was possible by culture. *Endothrix* is notoriously resistant to treatment unless epilated by x rays. Another patient, who refused x-ray epilation, was treated for nine months with local applications unsuccessfully and had to be x-rayed eventually. Case 22 is all the more remarkable as it became clinically and microscopically negative after 53 days' treatment, and has remained so for the last two months.

A new series of cases has been started on 5% salicylanilide in carbowax and Crill No. 6, and of 23 under treatment 10 cases of *M. felinum* have been cured after two to nine weeks and are still under observation.

Summary

A preliminary report is given on new advances in the local treatment of ringworm of the scalp, demonstrating that infections due to *M. audouinii* can be cured in a reasonable time without previous epilation.

With 0.5% phenylmercuric nitrate in carbowax and Crill No. 6, 22 cases were treated, including 8 of *M. audouinii* infection, 9 due to *M. felinum*, 4 due to unidentified microspora, and 1 due to *T. endothrix*.

Seventeen cases were cured in an average time of 2½ months.

In this small series of cases we found no significant differences between the responses to treatment of the human and that of the animal type of ringworm.

Preliminary epilation, even when followed by old-time remedies, still affords the quickest prospect of cure.

We are indebted to Dr. George Miller MacKee and Dr. F. Herrmann for helpful advice and reprints of their articles, and to

Mr. R. C. Syms, senior technician in the laboratory at St. John's Hospital, for his assistance with the mycology.

PREVENTION OF RINGWORM IN THE TROPICS

BY

HUGH R. JOLLY, M.B.Camb.

Late Dermatologist to Allied Forces, Netherlands East Indies

Ringworm is a far greater problem in the Tropics than in temperate climates, and for the British Army in the Netherlands East Indies (N.E.I.) in 1946 it was at one stage the commonest cause, apart from venereal disease, for admission to hospital. In February and March, 1946, ringworm accounted for 19.2% and 21.2%, respectively, of all admissions to a military hospital in Batavia receiving all types of cases except venereal disease. To these must be added the far greater number of cases treated by unit M.O.s, some having up to 50% of their men affected. These figures give a fair picture of the epidemic proportions which ringworm reached in this area. Furthermore, from discussions with colleagues in other parts of the East, I realized that these numbers were typical rather than exceptional for the Tropics.

To reduce this incidence was a military necessity of considerable urgency, in view of the fact that the N.E.I. was an active theatre of operations at the time. This paper describes a successful experiment carried out with 400 British other ranks (B.O.R.s) to test the efficacy of certain preventive measures which were later adopted on a much larger scale, and which may have a wider application to civil life as described later.

In temperate climates ringworm is largely confined to the feet, and from these it spreads to certain selective areas, notably the groins, axillae, and, in women, the sub-mammary regions. In the Tropics, however, it is much more widespread because of the profuse sweating, and although these selective areas are usually the first and more severely affected the whole of the skin may rapidly become involved. In this way a man might have two or three lesions one morning and within a few hours his body, including the face, might be covered with confluent ring-like figures consisting of vesicles and pustules round the edge of an erythematous area, which in the more severe cases would be moist or even weeping. The effect of this was to produce intense irritation; the body became covered with scratch marks, and the man no longer efficient as a front-line soldier. An associated and usually severe tinea interdigitalis, consisting of the typical white sodden skin between the toes, sometimes fissured and sometimes partially detached, occurred in 98% of the cases.

Mode of Spread

Most writers on ringworm emphasize the frequency of spread to the body from lesions between the toes; for example, Brain (1941) writes: "Tinea pedis is usually due the same organism as *trinea cruris* and, indeed, is often source of the groin infection, so that examination of feet in all cases of ringworm is important." Experience N.E.I. bears out this frequent mode of spread in tropical mates. Further, although some of the patients had failed notice their interdigital lesions, the majority stated that they had had them for some time before the ringworm on their body.

It must be pointed out, however, that the diagnosis of these cases was essentially on clinical grounds only, since conditions of active service at that time precluded any formal or large-scale microscopical surveys. Only four cases, picked at random, were examined microscopically, and in all of these the characteristic mycelium of ringworm was observed.

Some writers, notably Linn and Magarey (1941) working in Australia, have commented on the relative infrequency with which the fungus from lesions between the toes obtained, and obviously no direct answer can be given to this from the present experiment owing to the impossibility of carrying out the necessary investigations. However, the experimental method described here was based on the assumption that the lesions between the toes were due to a fungus infection, and the success of the experiment would appear to bear this out, at any rate in the Tropics.

The commonest method of spread between patients is undoubtedly via the feet, and in particular from bathroom floors. This is emphasized by Gray (1934), who quotes: "Legge *et al.* (1929), examining the feet of 3,100 transients to the University of California in one session, found 53.3% of the men and 15.3% of the women had ringworm. At the end of a year they again examined 100 of these men and 997 of the women who had access to the showers, swimming-pools, and gymnasiums. Of these, 78.6% of the men and 17.3% of the women were found infected. The increase in the case of the men is striking. The authors point out that the women students occupied a gymnasium with every known sanitary device. The women students and attendants were obliged to wear rubber shoes, and in no circumstances were they permitted to walk with bare feet on the floors or runways leading to the swimming-pools or gymnasiums. On the other hand, the men occupied an antiquated gymnasium where, on account of the lack or non-use of bathing shoes and inferior sanitary facilities, the students constantly walked on their bare feet and became infected." Fraser (1940) emphasized the importance of spread from bathroom floors and the need for careful foot hygiene to prevent it.

In view of these facts I believed that the main feature of a drive against ringworm must be the prevention of the spread of infection from the feet of one soldier to those of another. Consequently it was decided to carry out a large-scale field experiment on an air dispatch company consisting of 400 B.O.R.s. These men were employed on the loading and unloading of aircraft, which in tropical climates, with heavy loads, caused intense sweating: in fact, this unit was chosen because it was one in which working conditions were ideal for the development of severe ringworm, and one in which there was already a high incidence of the disease.

The Experiment

The success of the experiment would largely depend on the men, and therefore at the onset a brief talk was given to them by the unit M.O. and myself: here the rationale

of the experiment was explained, and in particular we pointed out that what the men called "foot-rot" was due to ringworm, and this could largely be prevented by frequent and thorough washing and drying between the toes. During the three months of the experiment each soldier was inspected once a week.

Equipment

Underpants.—Two pairs of cotton underpants were issued to each man, and these were washed on alternate days so that a clean one was available for wear each morning.

Foot-towels.—Each man was given two foot-towels, which were washed and changed daily. These were only used for drying the feet in order to prevent the spread of ringworm to the body from lesions between the toes.

Clogs.—Each man was provided with one pair of roughly made wooden clogs consisting of a shaped board with a single canvas strap. As showers were provided and not baths this made it possible to wash the toes without having to take off the clog, thus keeping the feet off the ground. Consequently the feet were never brought into contact with the bathroom floor, and this most important method of transference of infection was eradicated. As a corollary to this the men were instructed not to walk barefooted around the buildings.

Foot Powder.—This was kept in the bathroom, and the men were instructed to apply a little between the toes after drying.

Treatment

No attempt was made to segregate infected from non-infected men, and in fact this would have been almost impossible in the circumstances under which the men were living and working. It was also felt that the success achieved without this measure would add weight to the argument that the spread of infection was largely via the feet, since this was the one mode of spread which was being controlled. The routine treatment was of necessity modified in some cases, but the majority responded to the following measures.

Lesions on the Body.—1% chrysarobin in Lassar's paste was applied. It was never found necessary to increase the percentage of chrysarobin, so severe reactions to it seldom occurred.

Lesions on the Face.—Whitfield's ointment was used in place of chrysarobin, owing to the danger of conjunctivitis with the latter.

Lesions Between the Toes.—Brilliant green 1 in 500 in spirit, with 3% salicylic acid, was applied.

Results

June 1, 1946, was the starting date for the experiment, and on the previous day all the men were examined. Since up till then no record had been kept of the ringworm cases the figures

Graph showing total number of cases under treatment for each week of the experiment.

that cases occurring at the end of the three months were much less severe and less extensive than the early ones. The second part of the Table gives an analysis of the site of the lesions, and shows the rarity of ringworm of the body without an associated *trinea interdigitalis*, since only two cases occurred and both were present on the original inspection. The fall in the numbers of cases affecting body and toes will be seen

to be much more dramatic than the more steady fall in the number of cases affecting the toes only. This is explained on the theory, already outlined, that the earliest lesions are almost always between the toes, and that during the experiment the spread from toes to body was largely prevented by early treatment and the use of foot-towels.

Month	Average Time Taken for Cure	Distribution of Lesions in New Cases			
		Feet and Body	Feet Only	Body Only	Total
May ..	—	41	48	2	91
June ..	14.75 days	2	21	0	23
July ..	8.5 "	2	18	0	20
August ..	7.75 "	3	10	0	13

Relapse Rate.—There were no relapses in June, but five occurred in July and five in August—eight of these were cases of *tinea interdigitalis* only. However, in order to give a fair picture of the total ringworm state of the unit these have been included under new cases.

Discussion

It is emphasized that this experiment was carried out without alteration in the normal working routine of a very active unit, and in fact, because of the essential operative work on which the men were employed, it was very often necessary for a man with ringworm to miss one of his daily treatments. Therefore it is practicable not only for an active unit but also for immediate application in the wider field of civil life. Outbreaks of ringworm, particularly *tinea interdigitalis* and *tinea cruris*, are liable to occur in any civil community where communal washing facilities are provided, and especially in schools, factories, and mines.

Summary

A description is given of a successful experiment designed to reduce the high incidence of ringworm among troops in the Tropics. The importance of the spread of the disease via floors, from lesions between the toes (*tinea interdigitalis*), is emphasized, and this is made the basis of the preventive measures adopted. The application of these findings to civil life is noted.

The success of the experiment was largely due to Captain John Middleton, R.A.M.C., regimental medical officer to the unit concerned, to whom I am most indebted. I would like to thank the Director-General, Army Medical Services, for permission to publish, and Lieutenant-Colonel C. F. Mitchell, R.A.M.C., adviser in dermatology to the War Office, for his encouragement and assistance.

"The School Dental Service has substantially recovered from the wartime relapse due to the calling up of dental officers, but we still have a long way to go to make it truly comprehensive and efficient," said Mr. George Tomlinson, Minister of Education, speaking in London on April 3 at the annual dinner of the Dental Officers Group of the Society of Medical Officers of Health. Stating that the average interval between periodic inspections was still a good deal more than twelve months and needed to be reduced, Mr. Tomlinson said that nearly 70% of the children in schools had dental inspections in 1946 and that 72% of those found to need treatment were willing to accept it. Almost every local education authority had now appointed a senior dental officer, and it was expected that the few stragglers would soon come into line, but the expansion of the service was hindered, as with other parts of the educational system, by shortage of labour and materials. Much could be done by improvisation, however, and local education authorities were encouraged to provide additional clinics by taking over existing buildings and adapting them cheaply. Emphasis on preventive rather than curative aspects of dentistry was becoming more common. Nutrition was a vital element in this, and the school dental service together with the school milk and meals service and the school medical service formed a great co-operative enterprise designed to foster the physical welfare of the children.

EFFECTS OF SEX AND THYROID HORMONES ON THE PROCESS OF AGEING IN FEMALE RATS

BY

V. KORENCHEVSKY, M.D.

(From the Gerontological Research Unit, Oxford¹)

This paper is a summary of the results of experiments published in detail in four previous papers (Jones and Korenchevsky, 1946; Korenchevsky and Jones, 1946, 1947, 1948), and contains the general conclusions to be drawn from them. The effects of ovariectomy and of androsterone, oestradiol benzoate-butyrate, progesterone, and thyroid hormone, given alone or in various combinations, were investigated on the process of ageing in ovariectomized rats. All these hormones, including the androgenic hormone androsterone, are naturally present in the female organism. The literature relating to some parts of this subject is extensive and it was reviewed in detail in the previous articles. Therefore, for economy of space, the papers of only a few workers are here referred to. For the same reason our previously published detailed tables are summarized in three abbreviated tables and the illustrations are omitted.

Main Lines and Methods of Gerontological Research

The best definition of old age was given by Prof. Warthin (1930): essentially old age is a major involution of the organism, of all its vital organs and tissues and of all their functions. Surprisingly, this ageing involution starts in most organs very early, at childhood. Therefore gerontological research can be carried out on individuals of any age. Hence there are two chief approaches to gerontology: *research on ageing in young or adult individuals* (as in the present experiments) and *research on actual old age or senility in old animals or old human beings*. It is obvious that both these ways are equally important. For therapeutic purposes of geriatrics the investigation of ageing in the earlier years of life is of great importance, since it might contribute to the problem of prevention of the present premature and abnormal senility.

The ageing involution of at least some organs should first show itself in the decrease in their relative weight, i.e., in the relative hypoplasia of organs (Korenchevsky, 1942). On the other hand, if any factor has some anti-ageing effect on a certain organ, it should increase its weight and produce hypertrophy of that organ. Obviously the changes in weight of organs alone cannot be sufficient for conclusions on hypertrophic, atrophic, or especially on any degenerative changes. For this purpose at least histological examination is necessary in order to eliminate errors in cases of enlargement of the organs due to oedema or hyperaemia, and to discover degenerative changes, etc. However, a complete understanding and an accurate definition of the processes of ageing and of the anti-ageing properties of any factor examined could be obtained only after the performance of several morphological, physiological, and biochemical investigations, both experimental and clinical.

Technique of the Present Experiments

Five experiments were performed on 197 female rats, of which 11 were normal controls, 29 ovariectomized controls, and 157 ovariectomized rats treated with hormones. The

¹ I should like to express my gratitude to Lord Nuffield for the grants which have made possible the establishment and work of the Gerontological Research Unit, and to Prof. A. C. Hardy and Prof. E. G. T. Liddell for the kind hospitality extended to the Unit in the Departments of Zoology and Physiology of Oxford University.

duration of Experiments I and II was 56 to 76 days, and of Experiments III-V, 43 to 52 days.

Besides these five experiments a re-examination and a recalculation were made from some other earlier experiments in which a total of 54 normal and 325 ovariectomized rats were used in order to study the effects of ovariectomy and oestradiol administration. In different experiments the weights of organs might vary, and those of the experimental groups have to be compared with the weights of the respective control groups of each experiment. All sex hormones in experiments I-IV, and oestradiol benzoate-butyrate in Experiment V, were injected in oily solution. Progesterone and androsterone in Experiment V were injected as a crystalline emulsion suspended in 5% gum acacia. Desiccated thyroid was administered by mouth with a pipette in the form of a sweetened emulsion. Thyroxine was injected subcutaneously.

Each of the hormones investigated, except progesterone, was administered separately or in various combinations with other hormones. Progesterone was always injected with oestradiol B-B. The following weekly doses were used.

Experiment I.—Desiccated thyroid, 105 mg. ("small dose"); oestradiol B-B, 0.015 mg. ("small dose"), injected for three weeks only, or 0.09 mg. ("large dose"), injected every week; androsterone 4.5 mg.

Experiment II.—Desiccated thyroid, 250 mg., + thyroxine, 8 mg. ("large dose"); oestradiol B-B, 0.015 mg., injected for the first three weeks and two last weeks ("medium dose"). The doses of oestradiol B-B. ("large dose") and androsterone were the same as in Experiment I.

Experiments III and IV.—Desiccated thyroid, 65 mg., three times a week; oestradiol B-B, 0.028 mg., during first week only; progesterone, 2 mg., daily during last 19 days.

Experiment V.—Desiccated thyroid, 60 mg., three times a week; oestradiol B-B, 0.015 mg., injected three times during first week only; crystalline suspensions of androsterone, 10 mg., and progesterone, 10 mg., injected every 8th or 10th day.

The following methods of investigation were used: weighing of the organs and body fat (as indicated by weight of the abdominal fat); examination of the size of the cells by outlining them on paper and weighing the paper replicas obtained; measurement of the nuclei; count of mitoses; usual histological examination of the sections stained with haematoxylin and eosin, and, for lipoids, with Sudan black. All organs were weighed after fixation in Bouin's solution, except brain and hypophysis, which were fixed in 4% formol-saline. The relative weights have been calculated per unit of "fat-free" body weights for reasons explained below.

All details of the methods used were given in the previous papers (Jones and Korenchevsky, 1946; Korenchevsky and Jones, 1946, 1947, 1948). All results obtained were statistically analysed by means of Fisher's t-test for small samples. For the greater part of the statistical analyses I am indebted to Mr. B. Benjamin, the head of the L.C.C. Statistical Bureau, and for the other part to my co-worker, Miss V. E. Jones.

Ageing Hypoplasia of Organs

When the relative weights of organs in our normal intact female rats were calculated in the usual way—i.e., without subtraction of body fat—a progressive decrease of these weights was shown with ageing. A confirmation of these results was found in Donaldson's (1924) data and, after their recalculation, in those of Prof. Freudenberger and his co-workers (1935-1939). Neither Donaldson nor Freudenberger *et al.* investigated the amounts of body fat. Such an omission might lead to serious mistakes for two reasons:

1) The size and weight of an organ are determined to a

greater or lesser extent by the amount of work which that organ has to perform independently of, or for the maintenance and functioning of, correlated organs and tissues; from this point of view the inert fat tissues cannot be compared with any active tissue—e.g., muscular, glandular, nervous, etc. (2) When compared with a thin animal, the large fat deposition in the body of a fat animal will, when the organs are calculated per unit of body weight, give a fictitious decrease in the organs.

Since we always weighed abdominal fat, using this value we could roughly calculate the total body fat in our experiments. From the age of about 30 to 50 days to that of about 800 days these "fat-free" weights show a decrease (relative hypoplasia of organs) in thyroid, thymus, liver, kidneys, spleen, and brain. This decrease, however, was less pronounced than in the Donaldson-Freudenberger data. and in some organs (ovaries, adrenals, hypophysis) was developing from the age of sexual maturity only, or sometimes (heart) even later.

Effects of Ovariectomy (Artificial Climacteric).—Ovarian hypoplasia and hypofunction are the foremost factors in producing the climacteric in the senescent female organism. Therefore from an experimental point of view the condition produced in the young or adult female organism by ovariectomy might be considered as an artificial, premature, and extreme "climacteric" of purely gonadal origin. Thus the investigations of the changes produced by ovariectomy might explain several features in the climacterical symptom-complex. Comparing the age at which it appears and the rate of its development, the relative decrease of organs in our experiments was more pronounced in ovariectomized rats than in the normal controls. So far this has been confirmed histologically in the case of sex organs, liver, kidneys, and thyroid. The interpretation of the changes in adrenals is more difficult. Thus, as judged by the rate of involution of organs, ovariectomy accelerates the process of ageing.

Effects of Hormones on Ovariectomized ("Climacterical") Rats.—Tabulated detailed data and photomicrographs were given in the previous papers. The chief aim here is to demonstrate those non-sex organs in which the changes obtained were definite and statistically significant. Some new unpublished data are included in the tables. In order to show that the effects of hormones are evident both in actual and in relative weights, Table I contains the actual weight of organs, while Tables II and III contain the relative weights per 200 g. of "fat-free" body weight. So far histological examination has been made of uterus, vagina, adrenals, thyroid, liver, and kidneys.

TABLE I.—Effect of Androgenic, Oestrogenic, and Thyroid Hormones, Administered Separately or Simultaneously, on Actual Weight of Organs in Experiment II

Organs	Ovariectomized Controls	Thyroid Hormone (Large Dose)	Oestradiol B-B. (Medium Dose)		Androsterone		
			Alone	+ Thyroid Hormone (Large Dose)	Alone	+ Thyroid Hormone	+ Thyroid Hormone + Oestradiol B-B.
Adrenals (mg.)	55	86	84	135	42	70	123
Hypophysis (mg.)	15.4	14.2	19.8	19.8	15.2	14.7	15.7
Liver (g.)	6.79	9.17	5.01	11.55	8.78	9.99	10.37
Kidneys (g.)	1.44	2.12	1.60	2.54	1.65	2.18	2.60
Heart (mg.)	768	1,123	813	1,200	893	1,162	1,110

Effects of Thyroid Hormone.—This hormone has both stimulating and depressing properties. The stimulation was definitely demonstrated with a suitable dose in hypertrophy of adrenals, liver, kidneys, heart, and spleen (Table I), and in the histological changes obtained. These results are in close agreement with those of previous workers, as was shown in our review of the literature on the subject (Korenchevsky and Jones, 1946, p. 327). Depressing effects have been observed in a decreased function of thyroid gland, a smaller gain in body

weight, and decreased fat deposition. These changes obtained in ovariectomized rats are in complete agreement with those found in the previous experiments on normal rats (Korenchevsky, Hall, and Clapham, 1943; Korenchevsky and Hall, 1944). Uterus and vagina remained atrophic, but their epithelium and the muscular cells were slightly better developed than those in control ovariectomized animals.

Effects of Androsterone.—The stimulating effects of androsterone are shown (Tables I and II) in increased weight of vagina, liver, kidneys, heart, and in slightly better gain in body weight and fat deposition. Histologically the following changes

TABLE II.—Return of "Fat-free" Relative Weights of Organs Towards or Up To the Level Present at Earlier Age After Simultaneous Administration of Oestradiol B.B., Androsterone, and a Large Dose of Thyroid Hormone in Experiment II

Organs	Normal Intact Control Rats		Ovariectomized Rats Aged 152 Days	
	Aged 65 Days	Aged 152 Days	Controls	Treated with Three Hormones
Adrenals (mg.) ..	79	68	51	111
Thyroid (mg.) ..	20.9	16.7	13.0	15.3
Liver (g.) ..	9.8	7.7	6.3	9.5
Kidneys (g.) ..	1.8	1.7	1.3	2.3
Heart (mg.) ..	786	871	714	1,000

were found: slightly better development of still atrophic uterine epithelium, and better development of all vaginal layers; larger liver cells and a greater number of large nuclei; larger renal tubules with enlarged lumens; in thyroid—a definitely more active columnar epithelium, with less colloid in follicles (i.e., a stimulation of the gland). Androsterone, however, had a definitely depressing effect on adrenals, as shown by their small weight and the smaller size of their cells and nuclei; their lipid content was also decreased. The involution of thymus was accelerated, as is the case with all male sex hormones.

Effects of Oestradiol Benzoate-Butyrate.—Oestradiol B.B. (Table I) exerts varying effects, depending on the dose administered. Since it usually depresses growth and gain in body weight, the examination of the relative weights of organs be-

TABLE III.—Return of "Fat-free" Relative Weights of Organs Towards or Up To the Level Present at an Earlier Age after Administration of Progesterone, Oestradiol B.B., Androsterone, and a Small Dose of Thyroid Hormone in Experiment V

	Ovariectomized Rats, aged 175 Days					Normal Intact Controls aged 52 Days
	Controls	Androsterone	Thyroid Desicc. (Small Dose)	Progesterone		
				+ Oest-radiol B.-B.	+ Oest-radiol B.-B. + Androsterone + Thyroid Desicc.

Heart (mg.) ..	670	730	905	777	831	1,009

comes especially important. The best results were produced by medium doses, which, besides the well-known hypertrophic effect on the uterus and vagina, increased the relative weights of the adrenals, hypophysis, liver, kidneys, and, in some experiments, of the heart. Small doses might have no effect, while comparatively large doses produce a less stimulating and more toxic action. Among the toxic effects, the metaplastic changes of the uterine epithelium and glands, the development of adenoma-like structure in thymus (Ross and Korenchevsky, 1941; Plagge, 1946), and the tumour-like enlargement of the hypophysis are very important. Histologically, non-toxic doses produced in adrenals enlargement of the cortex, enlargement of the fasciculate cells, and an increase in number of large nuclei. While small and medium doses usually do not change the structure of adrenals, except for the above-mentioned hypertrophic features, the larger doses produced atrophy and

degenerative changes in the reticularis cells, with a considerable hyperaemia of this zone and a lipid depletion in the glomerulosa. With non-toxic doses the cells became enlarged in liver and kidneys, in some experiments significantly; likewise their nuclei. With the doses of oestradiol used no definite changes were found in thyroid structure.

Simultaneous Administration of Thyroid Hormone and Oestradiol B.B.—This association of hormones produced a stimulating hypertrophic action on some organs which was more pronounced than with either hormone alone. This was shown in the weight of the adrenals, liver, and kidneys (Table I), and histologically in the cortex of the adrenals and, in some cases, in the liver and kidney cells.

Simultaneous Administration of Androsterone with Oestradiol or with Thyroid Hormone.—With both these combinations the two latter hormones had an important neutralizing effect on the depressing, harmful action of androsterone on the adrenals. This was shown both in weight of adrenals (Table I) and in the return of their histological structure towards or up to normal. On the other hand, a neutralizing effect of androsterone was evidenced histologically by some decrease of the thyroid depression produced by small doses of thyroid hormone. The changes brought about in the thyroid by large doses of thyroid hormone were resistant to this action of androsterone. Other organs showed chiefly the effects of thyroid hormone, the latter overcoming the effects of androsterone.

Simultaneous Administration of Three Hormones—Androsterone, Oestradiol B.B., and Thyroid Hormone.—This combination produced (Tables I and II) effects similar to those of thyroid hormone + oestradiol, and androsterone + thyroid hormone. The neutralizing action on pathological changes in the adrenals and thyroid gland was also present. Histologically the adrenals had a structure similar to that in normal rats (except for the large size of the gland and their cells). Metaplasia of the uterine epithelium and glands was still present, but otherwise, with this combination of hormones, the structure of both uterus and vagina was closest to that in normal rats.

Insufficiency of the Three Hormones Used in Obtaining Normal Anti-involuntary Effects.—Some of the toxic or pathological effects observed with the combinations of the hormones used could not be prevented by any one of them. It is known, however, that the metaplasia of uterine epithelium produced by oestrogens, or the adenoma-like transformation of uterine glands produced by a combination of oestrogens with androgens (Korenchevsky and Hall, 1938, 1940), or the development of abdominal fibroid tumours after treatment with oestrogens (Lipschütz and Schwarz, 1944; Lipschütz *et al.*, 1944) could be prevented by progesterone. Therefore it was decided to administer progesterone in various combinations with the three hormones already investigated.

Progesterone in Combination with Oestradiol B.B.—This combination had a definite stimulating action on the thyroid, adrenal cortex, kidneys, and liver (Table III), producing hypertrophy of their cells. Liver and adrenals and, in the experiment, kidneys and heart had significantly greater weight. Involution of thymus was accelerated, and all pathological changes in the uterine epithelium and glands were prevented. **When three or four hormones**—progesterone, oestradiol B.B., and thyroid hormone, with or without androsterone (Table III)—were administered simultaneously the pathological changes in uterine epithelium were also prevented; the depressing action of androsterone on adrenals was neutralized, as was to a certain extent the depressing effect of thyroid hormone on the thyroid gland; the cells and their nuclei in the fasciculate zone of adrenals, in liver, and in kidneys were hypertrophied. Histologically, the progestational changes were found in uterus and vagina, being intensified in uterus with an androsterone-containing combination.

Discussion

It was well established by previous workers that in an ageing organism it is possible to return the secondary sex organs towards or up to normal size and weight by administration of sex hormones. In the present experiments the combined administration of sex and thyroid hormones produced a similar return towards or to normal weight in such

organs as adrenals, thyroid, liver, kidneys, spleen, and heart. Moreover, as the data in Tables II and III demonstrate, by such treatment it is possible to bring back atrophied adrenals, liver, kidneys, and heart towards or to their relative weight present at the earlier age. It is necessary, however, to mention that these results were obtained in ovariectomized animals. The results of similar experiments on intact normal animals are under examination, and doubtably will reveal some important differences.

As shown in the present experiments, when examining the beneficial action of any factor on the process of ageing it is dangerous not to take into consideration the harmful effects which are present simultaneously with the useful ones. The harmful effects might become especially dangerous in prolonged treatment or with larger doses, although the favourable effect might be much more striking with larger doses (Tables I and II) than with weaker ones (Table III).

Summary

Experiments were performed in order to study the effects of ovariectomy and of oestradiol benzoate-butyrate, progesterone, testosterone, and thyroid hormone, administered separately or various combinations, on the process of ageing in ovariectomized rats. Involution of some organs, as shown by changes in their relative weights, was taken as an indication of ageing. Ovariectomy—i.e., artificial "climacteric"—as judged by relative involution of organs, accelerates the process of ageing in rats.

All the hormones investigated possess two more or less pronounced properties: a stimulating, in most cases hypertrophic, ion, and simultaneously in some cases a pathological or depressing effect, on uterus, vagina, preputial glands, thymus, spleen, and such vital organs as adrenals, thyroid, hypophysis, heart, kidneys, and heart, also on fat deposition and body weight. These effects were exerted on all of these organs and actions, or on some of them only.

The stimulation and hypertrophy of the organs and tissues during their structure nearest to normal was obtained when four hormones were administered simultaneously in suitable, excessive, doses. In this way a co-operation of useful properties and more or less complete neutralization of pathological effects occurred.

Thus simultaneous administration of the hormones may prevent some damaging effects due to hyperhormonization produced by a single hormone. Such hypersecretion of a single hormone is unnatural in the normal organism, in which all hormones are secreted simultaneously in a certain balanced way.

The plurihormonal treatment used stopped the ageing involution of some organs in ovariectomized rats, and, moreover, brought the relative weights of these organs towards or up to the level observed at a younger age.

The above-mentioned results, however, do not warrant a definite conclusion whether the hypertrophy developed in some organs by the hormonal treatment should be considered as a kind of artificially produced deformity or else, it appears to be, as some favourable check to the process of ageing. These results prove only that some processes of ageing can be influenced arbitrarily.

It is necessary to emphasize strongly that before we can use any agent as an anti-ageing factor, especially for therapeutic purposes, more manifold investigation than that of the changes in weight and histological structure of some organs in the present experiments must be made. For this purpose, both experimental and clinical, many-sided and prolonged pathological, biochemical, and physiological experiments are necessary.

It is obvious that a complete picture of the effect of plurihormonal treatment on the process of ageing will be obtained only with the use of a combination of all the main hormones, especially those of the adrenal cortex and hypophysis.

I am indebted to Messrs. Ciba Ltd., in particular to Dr. K. Scher, for a generous supply of sex hormones, and to Messrs. Roux Wellcome and Co. for desiccated thyroid.

SERUM IRON IN NORMAL WOMEN

BY

SVEN DAHL, M.D.

(From Bornholm County Hospital and Viborg County Hospital, Denmark)

It was Fontes and Thivolle who first demonstrated that minute amounts of iron circulate in the serum. Since then much work has been done on serum-iron analyses, but not until recent years have the methods in use been sufficiently reliable.

The normal values for serum iron have not yet been fully established. Some authors have reported sex differences in the serum-iron concentration, while others deny their existence. So far, the normal amounts observed vary between 0.035 and 0.22 mg. per 100 ml. Most authors estimate the serum iron to be about 20 γ per 100 ml. lower in women than in men. Altogether about 1,000 determinations have been carried out on 21 "normal" subjects. These cannot be said, however, to be sufficient to elucidate this problem, particularly as the technique employed by the various authors has varied. It is possible, too, that the serum-iron concentration may have changed somewhat (i.e., given slightly pathological values) in individuals who have been looked upon as healthy. For determination of serum-iron values it is essential to be careful in the choice of the "normal" individual, because serum iron is a very labile plasma element, the concentration of which is dependent on many factors—e.g., absorption and excretion of iron, size of the depots, haemoglobin production, breakdown of haemoglobin, etc. In order to be quite sure that "normal" individuals are used it is necessary to ascertain whether the diet of the person concerned has contained a sufficiency of vitamins and minerals with a suitable amount of vegetables and meat. Then all the states of deficiency that influence iron metabolism will have been excluded. In addition, it is necessary to make sure that he has not recently been suffering from an infection or, if so, that recovery is complete; for infections interfere with iron metabolism, as is evident occasionally from the occurrence of infection anaemia.

It seems probable that the greatest variations in serum-iron concentration will be found in women, for the blood lost during menstruation may reasonably be expected to reduce the amount of serum iron. Besides, most women go

through one or more pregnancies, which may be assumed to influence iron metabolism and therefore the serum-iron concentration. Finally, the life of a woman may be divided into three periods, the menarche and the menopause forming the borderlines. All these conditions suggest that the iron metabolism must be far more active in women than in men, as in the latter only pathological conditions may conceivably affect it.

While the normal values for serum iron obtained by individual authors vary to some extent, collectively they give a fairly good idea of where the limits are to be set. Heilmeyer and Plötnner (1937), Skouge (1939), Albers (1941), and Dahl (1945) give somewhat lower values than do other authors.

Present Investigation

Among the subjects in the present series in whom the above-mentioned requirements have been met, three showed a serum-iron concentration of only 68 γ per 100 ml. and one of 69 γ . The highest values measured were 194, 166, 154, 146, and 143 γ per 100 ml., while all the others were under 140 γ .

According to these findings it seems not improbable that in women the normal serum iron varies between 70 and 140 γ per 100 ml. If in a woman we meet with a value under 70 γ we are probably dealing with a case of sideropenia; and if the value exceeds 140 γ it is not unreasonable to assume that the case is one of sideraemia (perhaps physiological sideraemia). It is difficult to decide when increased values are pathological, but values over 200 γ per 100 ml. must be regarded as decidedly so.

Technique.—First Poul Wehmeyer and I tried the technique of Bröckner-Mortensen and Carsten Olsten (1940); but later I employed the method of Balle (1942) and Höyer (1943), which has proved to be rapid and very accurate. Briefly, the method is as follows:

Sufficient blood is withdrawn to give 3 ml. of serum. One can manage with 1.5 ml., but then the duplicate analyses can be carried out only on diluted serum, and this makes the error 2 to 4% greater. To 3 ml. of serum, 1.5 ml. of 6N HCl is added, and the whole shaken; this liberates the serum iron. When the mixture has been standing for 15 minutes, 3 ml. of 20 vol. % trichloroacetic acid is added, again shaking; this precipitates the proteins. After standing for a few minutes the mixture is centrifuged at 5,000 revolutions a minute for 30 minutes. To 3 ml. of the clear supernatant fluid 80 c.mm. of concentrated nitric acid is added, and also 0.8 ml. of 5N potassium thiocyanate solution. The result is read within 10 minutes in a Pulfrich photometer with a 50-mm. microcuvette and filter 553. The control solution consists of iron-free water with the addition of the above-mentioned reagents.

The haemoglobin determination and the red blood count were performed on venous blood immediately after its withdrawal; the blood was obtained from a median vein.

Results

Altogether 112 analyses were performed on blood from healthy women, and the results are recorded in Tables I, II, III, and IV.

TABLE I.—Serum-iron Determination on 9 Girls before the Menarche. The Average Value is 111 γ per 100 ml.

Age	Height (cm.)	Weight (kg.)	Hb%	Erythrocytes in Millions	Serum Iron in γ /100 ml.
9	121	22	90	4.72	100
11	146	39	102	5.02	136
12	130	28	99	4.69	102
13	147	36	102	5.11	116
13	148	36	91	4.89	126

14	151	44	97	4.98	83
14	160	52	88	4.18	136

In nine girls in whom menstruation had not yet started the serum-iron values were between 83 and 136 γ per 100 ml. (Table I). One girl whose first menstruation appeared 19 days before the examination (the first subject in Table II) showed a serum-iron value of 84 γ . In 63 women with normal menstruation the serum-iron concentration varied between 68 and 154 γ per 100 ml. In 16 women in whom the menopause had appeared it varied between 76 and 194

10-12	108.7	28-30	125.5
13-15	99.2	31-33	139.0

Table III). The average values for girls and elderly women are 111 and 113 γ per 100 ml. respectively, while the average for menstruating women was 105 γ . This indicates that the serum-iron concentration is somewhat lower in menstruating women than in the non-menstruating.

It has been asserted that this lower value in menstruating women is due to the loss of iron month after month. The

work here reported indicates that this theory is correct. In order to obtain further corroboration four perfectly normal women were examined throughout a menstrual cycle (Table IV). The examination showed that the serum iron reached its highest value immediately before the menstruation, while the lowest values were found during and immediately after.

In Table V the 63 serum-iron values obtained in menstruating women (from Table II) are grouped after the menstrual cycle.

Here, too, we find the same values shortly before the expected menstruation. The Chart illustrates the distribution of the serum-iron values obtained in the present series. It shows how the normal limits—70 and 140 γ per 100 ml.—are arrived at.

Summary

Determination of the serum iron has been carried out on 92 healthy females receiving an adequate diet. The five highest values were 194, 166, 154, 146, and 143 γ per 100 ml.; while the three lowest values were 68 γ .

The serum-iron concentration was found to be lower in menstruating women than in those not menstruating.

The theory that the lower serum-iron value in menstruating women was due to loss of iron month after month is confirmed to be proved by the results obtained.

REFRACTORY IRON-DEFICIENCY ANAEMIA TREATED WITH INTRAVENOUS SACCHARATED OXIDE OF IRON

BY

L. S. P. DAVIDSON, B.A.(Cantab.), M.D.
F.R.C.P.Ed.&Lond.

Professor of Medicine, University of Edinburgh

AND

R. H. GIRDWOOD, M.B., F.R.C.P.Ed., M.R.C.P.
Lecturer in Medicine, University of Edinburgh

In a recent article by Nissim (1947) the use of saccharated oxide of iron for intravenous injection is described. The following case is reported because the patient responded dramatically to parenteral iron therapy subsequent to the failure of the oral administration of iron in large amounts for long periods, supplemented at various times with ascorbic acid, thyroid extract, molybdenized ferrous sulphate, parenteral liver extract, and folic acid.

Case History

The patient, a woman aged 29, was first admitted to hospital on June 13, 1945, with a three-months history of breathlessness and fatigue. Her appetite and diet had always been satisfactory, she had never suffered from dyspepsia or diarrhoea, her periods were not excessive, and there was no evidence of any other source of blood loss. On examination there was no oedema. The nails, although brittle, were not flattened. Some atrophy of the papillae of the tongue was present. The liver, spleen, and lymphatic glands were not enlarged. Physical examination of the cardiovascular, respiratory, renal, alimentary, and central nervous systems revealed no pathological features. The patient's intelligence was below average.

A test meal showed that free hydrochloric acid was present in the gastric juice. There was no excess of urobilinogen in the urine, and the stool benzidine test was negative. Radiological examination of the alimentary tract revealed no abnormality. The haemoglobin was 30%; erythrocytes, 2,850,000 per c.mm.; colour index, 0.53; white cells, 2,800 per c.mm.; reticulocytes <1%. The sternal marrow contained numerous late normoblasts of the type seen in iron-deficiency anaemia.

There was no response to ferrous sulphate, 3 gr. (0.2 g.) thrice daily for 24 days, followed by 6 gr. (0.4 g.) thrice daily for 20 days. Supplements of ascorbic acid, thyroid extract, and liver extract were given in turn, with no beneficial results. Accord-

Fig. 1 showing amount of serum iron in normal non-pregnant women

Fig. 1 showing amount of serum iron in normal non-pregnant women. The Chart illustrates the distribution of the serum-iron values obtained in the present series. It shows how the normal limits—70 and 140 γ per 100 ml.—are arrived at.

ingly she was given a transfusion of 3 pints (1.7 litres) of blood, which raised the haemoglobin level to 68%. She was discharged on Aug. 7, and continued to take ferrous sulphate, 3 gr. three times a day, as an out-patient.

She was readmitted on May 1, 1946, with a haemoglobin level of 51%. Physical examination again revealed no explanation for the anaemia. The possibility existed that the anaemia was dependent on some failure of absorption, although neither clinical nor radiological examination of the alimentary tract had revealed any abnormality. Accordingly a fat-balance test was done, and absorption of fat was found to be normal. A liver biopsy showed no pathological change. Sternal puncture was repeated and a normoblastic marrow again demonstrated, although this time it was somewhat hypoplastic. As no response occurred to continued iron therapy, a further 2 pints (1.14 litres) of blood was given, and this raised the haemoglobin level to 68%. The patient was discharged from hospital on May 14 with instructions to continue taking ferrous sulphate, 6 gr. (0.4 g.) thrice daily.

She was admitted to hospital for the third time on May 5, 1947, with a haemoglobin reading of 38%; erythrocytes, 3,180,000 per c.mm.; colour index, 0.6; white cells, 2,000 per c.mm.; P.C.V., 23%; M.C.V., 72.3 c. μ ; M.C.H.C., 22.8%. A histamine-fast achlorhydria was found. Radiological examination of the skeleton showed no abnormalities. The stool benzidine test was repeatedly negative. A third sternal puncture showed numerous late normoblasts. Folic acid and molybdenized ferrous sulphate were in turn given a trial, but produced no haematological or clinical benefit.

It was now decided to try saccharated oxide of iron intravenously. The preparation was made up according to the method described by Nissim (1947). She was first given 10 mg. of elemental iron as saccharated iron oxide in 1 ml. of solution, the dose being increased to 20 mg., 25 mg., and 50 mg. on successive days. Thereafter she received 14 injections of 100 mg. in 10 ml. of solution over a period of approximately 50 days. During this period the haemoglobin rose from 36% to 90% and the red cells from 2,860,000 to 4,650,000 per c.mm.

Her general clinical state was now excellent. All therapy was stopped, and when the patient was seen again a month later her haemoglobin was 94%; erythrocytes, 4,690,000 per c.mm.; colour index, 1.

The maximal reticulocyte count of 3.2% was on the tenth day after the first intravenous injection of iron. The patient had marked reactions (sickness and rigors) with the last three injections, all of which were given very slowly.

Severe reactions have also occurred in several other cases of iron-deficiency anaemia which we have treated with a solution of saccharated iron oxide given intravenously. We would therefore suggest that further work is required on the preparation of solutions of iron for intravenous injection before parenteral iron treatment is used by general practitioners.

Medical Memoranda

Bilateral Tubal Gestation

The following case of bilateral tubal pregnancy encountered in Iraq is of particular interest as it occurred in a patient known to have salpingitis.

CASE REPORT

The patient, an Arab married woman aged 30, had had two children, aged 10 and 4. Following the birth of the second child she developed a discharge and was found to have a gonococcal cervicitis and salpingitis. Until her admission she did not conceive again. Her periods had been moderately regular, but the accuracy of this statement is open to doubt. She had been in hospital on several occasions during this time with lower abdominal pain and vaginal discharge, diagnosed as salpingitis, the last admission having been eight weeks before her present illness. Again gonococci were found in the cervical smear. She returned complaining of an attack

of left-sided abdominal pain and discharge, but in addition stated she had missed two periods.

On admission she was in no distress. The pulse was 90 and the temperature normal. There was tenderness in the left iliac fossa, and vaginal examination showed a little bloody discharge, normal uterus and cervix, and a tender, rather indefinite swelling connected with the left tube. A diagnosis of salpingitis, but with the reservation that an ectopic gestation might be present, was made, and she was kept in bed in Fowler's position and given sulphathiazole. The pain subsided, but four days later she had a sudden attack of severe right lower abdominal pain, with a rise in pulse rate and abdominal distension, associated with tenderness and fullness in the right fornix. A blood count showed: red cells, 4,000,000; white cells, 11,000 (75% polymorphs). She was not severely ill or distressed in spite of this, and laparotomy was not performed. The distension and pain decreased steadily, and it was not until fourteen days after this attack that laparotomy was undertaken. Then the physical signs had altered radically. The swelling on the left was more definite, and was a mobile mass in the left iliac fossa, not felt from the pelvis at all. The uterus was raised and displaced to the left, and there was a semi-cystic swelling in the right fornix extending up into the right iliac fossa.

Operation.—A lower midline incision was made under general anaesthesia. There was a typical left tubal pregnancy occupying the distal half of the tube, with no sign of leaking of blood into the peritoneum. This was removed. On the right there was a haematoma walled off by adhesions extending into the pouch of Douglas and up into the right iliac fossa. The blood clot was removed. There was no sign of a bleeding point, but the uterine end of the right tube was eroded completely through for about an inch (2.5 cm.), the ends being friable. There did not seem to be any doubt that the haematoma had originated from here and could only have been from a tubal gestation. The ends of the tube were ligated and the abdomen closed. Search for embryonic remnants in the clot was not successful, but considering the probable original size of the gestation this was not surprising. Section confirmed that the tumour removed was a tubal gestation, chorionic tissue being seen in the sections. Recovery was entirely uneventful.

COMMENT

Bilateral tubal pregnancy is rare, the last report of a case in the *British Medical Journal* being in 1937 by McIlrath. Cox and Steinberg (1942), in reporting a case, state that 80 cases are on record in readily available literature, but I cannot be certain whether McIlrath's case is included among these. A further case was reported by Tractenberg (1944).

The question whether the foetuses would have been simultaneously viable or not is a point of great interest in these cases, and is raised by Fishback (1939) in a general review of this subject; but, there being no visible remnants of the products of conception on the right side in the present case, no good comparison can be made. However, it is probable that the right foetus was younger than the left, as the latter gave symptoms only while the patient was in hospital, and it was not palpable on admission.

It will be noted that laparotomy was delayed in this patient, and a word of explanation might be of interest. In this part of Iraq non-urgent abdominal operations can be undertaken with complete safety, but operations for acute abdominal conditions carry an abnormally high liability to complications, most commonly an intractable ilcus. I can offer no explanation of this, but it has been the experience of several surgeons serving in this area.

The Royal College of Nursing has arranged, with the approval of the Ministry of Health, a course for nurses on venereal diseases to be held on May 31 to June 26. It will be open to trained nurses who have been employed for at least six months in a venereal-diseases department. An examination will be held at the end of the course and a certificate awarded to successful candidates. Information may be obtained from: Director in the Education Department, Royal College of Nursing, Henrietta Place, Cavendish Square, London, W.1.

Reviews

CUSHING

Harvey Cushing. A Biography. By John F. Fulton. Publication No. 13 Historical Library, Yale Medical Library. (Pp. 754; 150 illustrations. 30s.) Oxford: Blackwell Scientific Publications.

Many will have had the pleasure of reading this book already, but its virtues are so great that it is only just that it should be referred to in these columns. Harvey Cushing added to his great scientific reputation by his excursions into the field of medical history and biography, notably by his well-known *Life of Osler*, and it is only natural that Prof. Fulton's biography should invite comparison. The differences between the two biographies lie chiefly in the disparity between the two subjects. Both have used similar methods: there are long extracts from journals and letters linked by a narrative commentary.

Official biographies may be deadly dull when they are written during the lifetime of close members of the hero's family. Osler emerged perhaps a trifle over-sanctified. The "Life" is enlivened by many flashes of criticism, directed of course at personal traits rather than total achievement, and it is all the better for it. Prof. Fulton has performed his task with great discretion and with the warm sympathy and insight which would be expected from one closely associated with his subject for so many years.

Cushing and Fulton shared a devotion in different ways to the nervous system, but the lasting bond between them, besides a very great mutual liking, was their passion for the history of medicine. This love of old books had been the original link between Cushing and Osler during the former's formative years in Baltimore, and it was this pursuit that made Oxford a home in Europe for Cushing after Osler had gone there. It brought Cushing many warm friendships, notably with A. C. Klebs, who, though not so intelligent as Cushing, was a better scholar than he.

Prof. Fulton has traced all these interesting threads in a way that is at once clear and interesting. Cushing's contribution to his own subject of neurosurgery shines from these pages, though Prof. Fulton does not venture on an analytical appraisal of Cushing's work on brain tumours. He touches on Cushing's inability to give as much credit as he should have done to others, especially to Horsley. In his middle period Cushing came to look on himself almost as the owner of the surgery of the nervous system. But despite those blemishes the guiding principles in all his work were admirable, notably his belief in the unity of medicine, his desire that no specialty should become isolated, and his lack of interest in the money motive of personal advancement.

Cushing's life history is that of a man dedicated to a particular service. He streamlined himself by refusing the distractions that pull the average man now this way now that to the ultimate diminution of his achievement. No one has devoted himself more passionately to an ideal by giving himself up wholly to the study of a special field of medicine. It meant for Cushing, first, improvements in method; secondly, a better understanding of the nature of different intracranial tumours and their effects; thirdly, a further improvement in methods based on the second, and so forth endlessly.

We turn the pages of this book with wistful eyes as we read of the Continental congresses and scientific meetings freely attended by famous men of all nations and realize sadly how much we miss by our present-day immobilization. Perhaps the biographer has given too much prominence to these public occasions, though an official "life" must necessarily record them all. On the whole Prof. Fulton has written a well-balanced book about one of the most remarkable and dynamic men of our time.

GEOFFREY JEFFERSON.

JOINT DISEASES

Arthritis and Related Conditions. Edited by Theodore Franklin Bach, M.D., F.A.C.P. (Pp. 472; 139 illustrations. \$6.50 or 36s.) Philadelphia: F. A. Davis Company. London: H. K. Lewis and Co. 1947.

The late Dr. Garfield Snyder originally planned this book, but owing to his untimely death Dr. T. F. Bach and his collaborators took over the task. The result is a somewhat uneven and often diffuse work on many aspects of joint disease and associated conditions. It is intended for the general practitioner, but it is more suited to the student. Those who wish to extend their knowledge of a group of diseases difficult to understand will find it interesting; the opening historical chapters will particularly please them. The elaborate classification and the form recommended for recording the history and physical examination, excellent though they may be for the intern, may put the busy doctor off at the outset.

The authors give much attention to the problem of focal infection and emphasize its importance, but the absence of controls weakens the conclusions. In the account of the gall-bladder and intestinal tract the figures convey the impression that the incidence, especially of gall-bladder infection, might be nearly as great as in patients with no evidence of arthritis. The dietary recommended for the arthritic, excellent though it may be, is quite impossible for most patients in Britain to obtain, and the food advised for one day's consumption would be found difficult to provide for three days under the present rationing conditions. The authors pay scanty attention to fibrositis and overlook much of the important work done in England during the last few years. Possibly this form of rheumatism is not so frequently met with in the U.S.A. Some of the suggestions for treatment provoke criticism: the use of paraffin wax for packs with a melting point of 167-176° F. (75-80° C.) is rather startling; the wax used in Britain has a melting point of 122° F. (50° C.) and the maximum temperature to be reached in its application is 140° F. (60° C.). The chapter on functional disorders of the foot is one of the best and contains much original observation and practical advice on treatment within the province of the general practitioner. The section on manipulation, with the directions given for splinting and supports of various types, is likely to be very useful.

An excellent chapter is that on x-ray treatment, for it is comprehensive and contains detailed information, based on wide practical experience, not readily accessible in so compact a form. That on x-ray diagnosis, from a different pen, is by no means as satisfactory.

C. W. BUCKLEY.

SURGERY FOR STUDENTS

Surgery. A Textbook for Students. By Charles Aubrey Pannett, B.Sc., M.D., F.R.C.S. Second edition. (Pp. 769; illustrated. 27s. 6d.) London: Hodder and Stoughton. 1947.

Of late years the general surgeon has had to give ground to the specialist on every side, and most recently published textbooks have been written by groups of specialists. This method has both advantages and disadvantages. It is true that there are nowadays fewer surgeons who can claim the encyclopaedic knowledge which the modern textbook seems to require, but on the other hand we feel some sympathy with the remark of the author in the preface to this book: "It does not seem fair to expect the student to have more exact knowledge than his examiner possesses, or to have read a series of monographs by experts." Anyway, the author has practised what he preaches and has written the whole of this book—indeed, he has done more, for all the (nearly 400) illustrations are from his clever and artistic hand. The book contains the wisdom gained in the long and varied surgical experience of one of our most versatile general surgeons, who has himself contributed notably to the advance of three or four specialties.

When the first edition appeared during the war the reviewer found it a most readable and informative manual, but the production was very austere; in this edition it is much improved, and several additions have been made to the text. The book is in several respects unusual. The author considers anatomy,

pathology, bacteriology, and operative surgery only briefly and as occasion demands. He does not discuss differential diagnosis, for if the symptoms are well known that should be sufficient. Bold and obvious printer's types appear less than in most textbooks, and there are few lists to make their orderly appeal to the student. But a philosophic outlook pervades the book. The first sentence is arresting: "A knowledge of physiology is essential for the practice of surgery." That dictum ought to be in a prominent position on every surgeon's desk. Moreover, the author has a good style. His sentences are short and crisp and well adapted for descriptive purposes. For example, we have seldom anywhere seen such a mass of facts presented in such a clear, vivid, and readable manner as in the description of concussion on p. 118 and in the account of intestinal obstruction on pp. 363-5.

At present there is much talk of reforming the surgical curriculum, of the necessity to teach only essential facts with emphasis on principles, and of the need for a new type of textbook in conformity with these changes. This book is the nearest approach yet to such a textbook. It should gain in popularity.

V. ZACHARY COPE.

E.N.T. MANUAL

A Manual of Otolaryngology, Rhinology and Laryngology. By Howard Charles Ballenger, M.D., F.A.C.S. Third edition, enlarged and thoroughly revised. (Pp. 352; 135 illustrations and 3 coloured plates. 22s. 6d.) London: Henry Kimpton. 1947.

The author sets out to write a concise textbook for undergraduates avoiding the descriptions of operations, save for two or three minor ones and tracheotomy. He bases the *Manual* on the well-known *Diseases of Nose, Throat, and Ear*, by W. L. and H. C. Ballenger, but the task of compression is difficult and the result is not altogether happy. Most of the knowledge is there, but its arrangement is not satisfactory. The accounts of common conditions and diseases receive no more prominence than rarities—for example, in the section on diseases of the external auditory meatus he discusses herpes oticus first and wax last.

There are four parts. The first, on the nose and sinuses, begins with an excellent description of the common cold. The author then discusses acute inflammations of the sinuses and advises irrigation through the normal openings, which is a treatment scarcely suitable for a student to carry out. Some statements call for criticism: "redness and swelling over an acutely inflamed sinus" a condition very rarely seen; "transillumination is a satisfactory means of diagnosis of frontal sinusitis . . . x-rays are not so good"; and he regards retrobulbar neuritis as the most important among the complications of sinusitis. The chapter on headaches and neuralgias of the face and head, a new one in this edition, is good, and he mentions all the causes and includes references to the original papers.

Part II is on the pharynx and fauces. Besides the usual accounts of diseases of tonsils there is an excellent list of indications for their removal, and a chapter on deep neck infections with helpful diagrams.

In Part III, on the larynx, the illustrations of anatomy and pathology are good. The chapter on paralysis of the larynx is written by J. J. Ballenger; he has designed an ingenious diagram to show the nerves to the larynx and how the paralyses are produced. There is no mention of fixation at the cricoarytenoid joint, but "syphilis of the larynx may produce paralysis of one or both cords"—a somewhat loose statement.

Part IV is on the ear and is perhaps the best part of the book. The illustrations showing how to carry out tuning-fork tests are new and will certainly help the student. As in other sections emissions are curious—there is no mention of masked mastoiditis, nor is facial paralysis recorded as an indication for operation. On the other hand the account of petrositis is excellent. The illustrations (135 in number) are all clear; there are also three colour plates.

W. M. MOLLISON.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

La Maladie Hémolytique du Nouveau-né By M. Bessis. (Pp. 260. 600 francs.) Paris: Masson. 1947.

An account for the clinician and laboratory worker, with reference to the author's own researches.

Éléments de Physiologie Psychologique. By P. Rijlant. (Pp. 216. 360 francs.) Liège: Masson. 1948.

Discusses the anatomy and physiology of the nervous system and their relation to mind.

Le Développement Psychique de l'Enfant et de l'Adolescent. By E. Pichon. (Pp. 240. 420 francs.) Paris: Masson. 1947.

The author discusses abnormal as well as normal development.

La Penicillina in Chirurgia. By S. Ciancarelli. (Pp. 46. No price.) Rome: Luigi Pozzi. 1948.

The author describes his technique of local injection of penicillin.

La Chirurgie Biliaire. By P. Mallet-Guy et al. (Pp. 138. 1,200 francs.) Paris: Masson. 1947.

An account of the surgery of the biliary apparatus with manometric and radiological control.

Confrontations Radio-Anatomo-Cliniques. Vol. II. Edited by M. Chiray et al. (Pp. 67. 1,200 francs.) Paris: G. Doin and Masson. 1947.

Notes on a variety of cases, with skiagraphs.

Les Tuberculines. By Dr. L. Vannier. (Pp. 460. 495 francs.) Paris: G. Doin. 1947.

The author describes his method of immunizing people predisposed to tuberculous infection.

Journées Thérapeutiques de Paris, 1946. Edited by Prof. M. Loeper and Dr. L. Bory. (Pp. 475. 980 francs.) Paris: G. Doin. 1948.

Includes papers on iron as a therapeutic agent and on the use of aerosols.

Nouvelle Pratique Chirurgicale Illustrée. Part I. Edited by J. Quénu. (Pp. 273. 550 francs.) Paris: G. Doin. 1948.

An illustrated practical manual.

Lehrbuch der Geburtshilfe. Vols. I and II. By T. Koller. (Pp. 613 Vol I and 1,323 Vol. II. 110 Swiss francs.) Basle: Verlag von S. Karger. 1948.

A textbook of obstetrics, including an account of foetal malformations.

Plutisologie Infantile. By P. Lowys. (Pp. 716. No price.) Paris: Editions Médicales Flammarion. 1947.

A general account of tuberculosis in childhood.

The Foundations of Health in Childhood. By Prof. N. B. Capon, M.D., F.R.C.P. (Pp. 76. 2s. 6d.) London: The Convocation Lecture, 1947, of the National Children's Home.

The main factors determining the health of the child in infancy are discussed.

Factors Regulating Blood Pressure. Edited by B. W. Zeitach and E. Shorr. (Pp. 175. \$1.90.) New York: Josiah Macy, Jr. Foundation. 1947.

Collection of papers read at a conference in 1947.

Textbook for Almoners. By D. Manchée. (Pp. 466. 27s. 6d.) London: Baillière, Tindall and Cox. 1947.

A general account of the almoner's functions and duties.

Children by Choice. By Dr. E. Chesser. (Pp. 127. 5s.) London: Torchstream Books. 1947.

A practical manual of birth control for the layman.

1947 Year Book of Obstetrics and Gynecology. Edited by J. P. Greenhill, M.D. (Pp. 590. 21s.) London: H. K. Lewis. 1948.

A synopsis of recent advances.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY APRIL 17 1948

MR. BEVAN'S GESTURE

Since the publication of the plebiscite results the medical profession and the Minister of Health have avoided direct contact with each other, but have also avoided making statements that would make renewed discussions impossible. At the Special Representative Meeting on March 17 he Chairman of Council, Dr. Dain, made this highly significant statement: "We are ready to enter into any discussions directed to making it possible for the medical profession to co-operate with the Government. If the Government can show us other ways, new ways, of preserving our independence we are willing to listen." In the same week the Royal College of Physicians of Edinburgh submitted a number of resolutions to the Prime Minister urging the resumption of negotiations and drawing attention to the fact that the fears of the profession centred round the power of the Minister to alter by Order or by Regulation the fundamental terms of service of the profession. On April 4 the Royal College of Physicians of London made public the resolutions passed by the Comitia on March 22 and forwarded them to Mr. Aneurin Bevan. These resolutions reaffirmed the opposition of the College to a whole-time medical service, requested an amending Act to prevent the introduction of such a service by Regulation, and suggested that Regulations affecting the National Health Service should be subject to special procedure. In the House of Commons on April 7 Mr. Aneurin Bevan made a statement to the House in which he undertook to make statutorily clear that a whole-time service would not be brought in by Regulation. Mr. Bevan also suggested important modifications of his previous proposal for a universal basic salary. He suggested that all new entrants to practice should have "this assured element of £300 or a period of, say, three years." After that the practitioner could decide whether to continue with the fixed element of £300 plus capitation fees, or to be remunerated by "plain capitation fees"—at a higher proportionate rate than when he was receiving the fixed element of £300. Mr. Bevan said:

"So now it can rest with the individual doctor himself to decide the extent to which he prefers the combined system of £300 plus lower capitation, or all capitation—with the exception that beginners will start with three years on the former system."

In reply to questions put by Mr. Clement Davies, Mr. Wilson Harris, and Dr. Segal, he reiterated his wish

to discuss these matters with representatives of the medical profession. On the day following his statement—April 8—he announced the composition of the Legal Committee set up to inquire into the meaning of Section 35 of the Act, two of the members of this Committee being Sir Cyril Radcliffe and Mr. J. H. Stamp, whose opinion on this Section was sought by the B.M.A. last year and published in the *Supplement* of Dec. 20, 1947. On April 8 the National Health Service Executive Committee of the B.M.A. Council met to consider the new situation and issued a statement welcoming the observations made by the Minister, and inviting him to receive a deputation to consider a series of written questions put to him in advance of the meeting. The B.M.A.'s questions and the Minister's answers are published elsewhere in this issue, and were considered by the Council on Wednesday.

Mr. Oliver Stanley, Conservative M.P. for Bristol West, made this comment on Mr. Bevan's statement: "I am sure that, speaking for everyone on this side of the House, we welcome anything which tends to break the deadlock which has occurred, and above all we welcome the tone in which the right hon. Gentleman has spoken to-day." We believe that the medical profession will be equally generous in echoing Mr. Stanley's comment. Mr. Bevan has made a gesture of conciliation, and has taken steps to meet two of the principal objections of the medical profession to the present Act. The B.M.A. deputation has now put for his consideration other points of dispute. While we await the outcome of these discussions we should recognize that Mr. Bevan has taken the result of the plebiscite into serious consideration by making proposals with which many in his own party will not be in sympathy.

The Presidents of the three Royal Colleges have come in for much criticism as a result of the letter addressed by them to the Minister of Health in January of last year. The recent action of the Royal College of Physicians of London is coming in for renewed criticism of a similar kind. Those who so criticize should bear in mind that consultants have been pressing their Colleges to make a statement on the present position, and we expressed the hope in a recent leading article¹ "that the Colleges will discover what are the views of their Fellows and take steps to make them public." It is therefore unreasonable and unfair to belabour the Royal Colleges for making a corporate expression of opinion. In a leading article in the *Journal* of March 20 we stated: "We believe Mr. Bevan when he says that it is not his intention to introduce such a service [i.e., a whole-time salaried State medical service], and it is no reflection on him to say that this expressed intention is no safeguard to the medical profession. . . ." And we continued thus: "There is nothing in the present Act which offers the safeguard required, and the logical conclusion is that nothing short of an amending Act would provide this safeguard." The Comitia of the Royal College of Physicians on March 22 passed its resolution requesting such an amending Act, and on April 7 Mr. Bevan agreed to introduce one. It would be undignified to indulge in a squabble for priority for a suggestion that has been fairly widely mooted, and in a country where freedom of

¹ *British Medical Journal*, 1948, 1, 550.

² *The Times*, Jan. 16, 1948.

³ *British Medical Journal*, 1948, 1, 53.

opinion is held dearly it would be, to say the least of it, paradoxical to challenge the right of any organization to state its opinion on a matter that is the concern of everyone. One of the principal arguments against the National Health Service Act has been that it leads to a whole-time State medical service. Mr. Bevan's proposal means that no such service can be introduced through the issue of Regulations. If any future Government were to attempt to introduce a whole-time State medical service it would have to introduce a new Bill which would be submitted to public debate in Parliament and on which the medical profession would have full opportunity to make its views heard; and we may note here that the plebiscite conducted by the B.M.A. has had its effect in persuading the present Government to introduce a safeguard that has been demanded by the medical profession.

The second resolution of the Royal College of Physicians has received less attention than the first, and was not referred to in the House of Commons by Mr. Bevan. It was on the same lines as the resolution passed by the Royal College of Physicians of Edinburgh. Both these Colleges drew attention to the power possessed by the Minister to change by Regulation the character of the National Health Service, and the London College suggested "that an amending Bill should be introduced to make Regulations affecting the National Health Service subject to special procedure." But in his reply (No. 7) Mr. Bevan is not impressed by this proposal. The powers of the Minister under the Act are considerable and, indeed, alarming. We understand that the special procedure suggested in the College resolution is neither impracticable nor unconstitutional. Under such a procedure proposed Regulations published in draft are submitted to a commission given power to reject or amend if it can be shown that the Regulations would change the character of the Service. Such a commission would have on it members of the two Houses of Parliament and medical and legal representatives. At a time when so many activities of the people of this country are governed by Regulations that pour out in a steady stream from departments of State, some such procedure as this would seem highly desirable, and in the case of the medical profession would offer a much needed and additional safeguard against meddlesome bureaucracy.

Of the much publicized four points, the one that has received most emphasis and most opposition is the universal basic salary. As there seemed to be no logical reason for forcing men in established practice to receive part of their remuneration in this way, general practitioners not illogically saw this as the first possible step to a full salaried medical service, and in any case linked to the control of certification. In a recent letter to *The Times*² Dr. Dain said: "We would support Mr. Bevan if he used the basic salary to induce men to serve in difficult areas, or to help the young man entering practice." In a leading article in this *Journal* about the same time³ we observed: "It should be clear that no objection has been raised to the use of the salary to attract men into difficult or undesirable areas or even to help the young man entering practice for the first time." Mr. Bevan by his statement

has removed the objection to the universal basic salary. While we recognize that this is a big concession on his part, his suggestions in the Commons introduce anomalies that are not entirely satisfactory. We would stress the questions of need and equity. For example a man may enter general practice as a partner and would therefore not need a guaranteed minimum salary. Again a proportion of men in practice exercising the option for a basic salary would be better remunerated for the same work than those who did not exercise the option. Mr. Bevan (Reply No. 8) now expresses his willingness to discuss with the profession the conditions and methods by which opting will be conducted.

Mr. Bevan's answers came too late for full comment in this issue. We note in particular his observations on the preservation of professional freedom with the abolition of buying and selling practices: doctors, for example, will be free to choose their partners and assistants. The medical profession has committed itself to a comprehensive medical service for the whole community, and such a service has the support of all political parties, Mr. Bevan's Act being the final outcome of plans laid down by a Coalition Government. The medical profession must also recognize that Mr. Bevan, after violently attacking the medical profession in a debate earlier this year, has sought to resolve the deadlock by using temperate and conciliatory words in putting forward his new proposals. There is, therefore, everything to be gained in responding to this gesture in a similar manner.

THE CHEMOTHERAPY OF CHOLERA

The cholera vibrio is one of the few organisms which seemed completely to have escaped the chemotherapeutic net. The treatment of cholera remained symptomatic, and consisted largely in combating the intense dehydration of the tissues by hypertonic saline rather than in destroying the vibrios. Attempts had indeed been made to combine sulphaguanidine with hypertonic saline, but without any conspicuous success. In view of the impotence of chemotherapy it is therefore not surprising that in many outbreaks, especially where skilled nursing was unavailable, the mortality rates remained high. In our issue of April 3 (p. 650) we drew attention to a preliminary communication by Bhatnagar and his colleagues¹ in which they described a new chemotherapeutic approach to cholera. In our present issue (p. 719) we publish in full the data at present available on the treatment of cholera by a new sulphamide compound, provisionally termed "6257."

The starting-point for this investigation was an observation made by Bhatnagar in 1939 that hexamethylenetetramine in a 10% solution in normal saline killed the cholera vibrio in less than half an hour, even when the organisms were in high concentration. Attempts to link hexamine and sulphanilamide produced compounds which gave promising results in the treatment of animals experimentally infected and in human cases of cholera, but a

¹ Bhatnagar, S. S., Fernandes, F., De Sa, H., and Divekar, P. V., *Nature* 1948, 161, 395.

² Meier, R., *Schweiz. med. Wschr.*, 1946, 76, 695.

³ Druey, J., *Helv. chim. Acta*, in press.

hance discussion revealed that Meier² and Druey³ had evolved a new product, 6257, by the condensation of two molecules of sulphathiazole and three molecules of formaldehyde. The exact constitution of the new compound is at present uncertain, though its formula is given as $C_{12}H_{12}O_4N_4S_3$. If it is really a condensation product and not, as are most sulphonamide derivatives, a substitution product, or an addition to the radicals of sulphanilamide, it represents a type of compound the chemotherapeutic possibilities of which have not yet been fully explored.

Preliminary *in vitro* experiments showed that 6257 was bacteriostatic or bactericidal against the Inaba and Ogawa strains of *Vibrio cholerae*. Owing to the relative insolubility of the drug in water it had to be tested as a 20% suspension in 2% gum arabic in distilled water. In mice the therapeutic activity was tested against the Inaba strain, twice the minimal lethal dose of organisms being given intraperitoneally. The effectiveness of the drug was considerably greater when it was administered intraperitoneally or subcutaneously than when it was given by mouth. This is apparently due to the fact that it is very slowly absorbed after oral administration. Even when injected absorption into the blood stream is slow, but as excretion also is slow it is possible to maintain in the blood of mice an effective therapeutic level by an initial dose of 80 to 90 mg. of the drug, followed by 40 mg. a day for four days. Subcutaneous or intraperitoneal injection does not cause any irritation despite the formation of a local depot.

Field trials were undertaken in the south-eastern part of the Madras Presidency during November and December, 1947. Records for the past seven years show that the infection is endemic in this area—the maximum incidence, with a case mortality of about 60%, being from September to February. The patients, who were mostly of the "untouchable" labouring classes, were all suffering from malnutrition, and were treated in their homes without any nursing or general medical care. No additional treatment in the form of salines or other palliatives was given. All cases were diagnosed bacteriologically before beginning treatment and were then classified into three groups according to the severity of the disease and the length of time during which the patients had been ill. In all, 85 patients were treated, and of these 82 survived. The average amounts given were 16 g. for a child, 23 g. for an adult female, and 25 to 30 g. for an adult male. The subcutaneous route was first tried, but, contrary to what had been found in the mouse suffering from a cholera septicaemia, in man there was little or no therapeutic action. The drug was therefore given by mouth, with good results. To overcome the tendency to vomit, 0.5 g. tablets were broken up and given in small amounts, till the full dose of 6 g. had been ingested in the course of two to three hours. If this practice did not succeed, the drug, suspended in gum arabic, was given per rectum. The improvement, even in 24 hours, appears to have been remarkable, as purgation was reduced and nausea, vomiting, and cramps disappeared. Within forty-eight hours the temperature had risen to normal and dehydration was much less marked. As a rule patients could be said to have recovered at the

end of seventy-two hours. Nevertheless, to ensure destruction of vibrios in the stools, a seven-day course of treatment was considered advisable. For adults the first day's dose was 10 g., the second day's 4 to 6 g., and thereafter 4, 2, and 1 g. per day. No toxic results were noted even in the most severely ill patients, a result which Bhatnagar and his colleagues suggest is due to the presence of the formaldehyde radical. It is remarkable that out of the whole series only three patients died, and they were in the group of those most seriously ill.

Though since the pathogenicity of cholera vibrios is known to vary greatly in different epidemics it would be rash to assert that a panacea for cholera has been obtained, nevertheless the results achieved in Madras and described in the opening pages of this issue are so striking that they merit further investigation on the widest possible scale.

REFRACTORY IRON-DEFICIENCY ANAEMIA

When Sydenham, in 1681, first advocated the use of iron he wrote that "to the worn out or languid blood it gives a spur or fillip whereby the animal spirits, which before lay prostrate and sunken under their own weight, are raised and excited." In most patients with hypochromic anaemia its beneficent action has justified his description, and the satisfactory results constantly obtained since the re-introduction some twenty-five years ago of adequate oral dosage have thrown into sharp relief the occasional instance in which iron cannot be tolerated or is ineffective. A small number of persons are genuinely intolerant of all preparations of iron given by mouth; in them even small doses cause abdominal pain, vomiting, and purging. In a somewhat larger number full doses may be ineffective even when the anaemia is undoubtedly due to iron deficiency.

A defect of absorption has long been considered as the cause of these refractory cases. The exact mechanism of the process is still uncertain, but Hahn and his colleagues^{1, 2} have shown that the quantity absorbed depends on the depletion of the body's reserves of available iron, and Granick's observations suggest that the iron-protein-phosphorus complex ferritin is concerned in its absorption from the alimentary tract. Studies of the serum iron have also thrown some light on the subject. The normal levels are accepted as 94–174 γ per 100 ml. for males and 58–142 γ per 100 ml. for females.³ Dr. Sven Dahl's paper in this issue confirms these figures for women, and again demonstrates the fall with menstruation. In iron-deficiency anaemia the level of the serum iron is decreased, commonly to 15–40 γ per 100 ml. Five hours after a single dose of iron by mouth it rises to a peak, which may exceed 500 γ per 100 ml.⁴ Powell⁵ was able to show that there was no such rise in refractory cases, though in some of these a peak did occur when iron was administered concurrently with large doses of ascorbic acid, an effect attributable to the preservation of the ferrous state by the reducing action of the vitamin. A group resistant to treatment with iron by mouth remained in which no rise in the serum iron level took place.

Obviously it is in this group that parenteral administration might be thought desirable, but some eminent authorities have objected to injections of iron as "impractical, dangerous, and unnecessary."^{6,7} The occasional necessity for parenteral treatment can no longer be denied, for there is abundant proof that hypochromic anaemia responds satisfactorily to iron administered in this way. It was thus used as long ago as 1872 by Rosenthal, and in the pages of this *Journal* for 1893 Stockman⁸ recorded a rise in the erythrocyte count and the haemoglobin level in chlorotic patients after subcutaneous injections of iron sodium citrate. Recent work has shown that the injected iron is used almost quantitatively for the formation of haemoglobin.^{6,9} It has been estimated that an adult with hypochromic anaemia requires 24.5 mg. of elemental iron if the haemoglobin reading on the Haldane scale is to improve by 1% per day. There is no doubt, therefore, that iron is effective when injected, but there remain the dangers. Many authors have reported alarming sequelae to even moderate doses: sneezing, lacrimation, paraesthesiae, flushing, headache, tachycardia, vomiting, diarrhoea, pleuritic pain, and circulatory collapse are all recorded.⁹

Descriptions of reactions have been sufficient to deter most physicians, but a paper published last year by Nissim¹⁰ has revived interest in this important topic. He found that a solution of saccharated iron oxide could be prepared which caused no serious reaction when injected intravenously in quantities containing as much as 1,000 mg. of elemental iron. In this number of the *Journal* Prof. L. S. P. Davidson and Dr. R. H. Girdwood report an example of refractory iron-deficiency anaemia successfully treated by this method. Reactions occurred with the last three injections of 100 mg. of iron, and the authors do not feel that Nissim's solution is yet to be recommended for general use. In a letter to the Editor, also in this issue, Drs. H. G. B. Slack and J. F. Wilkinson mention their use of a similar preparation and promise a detailed description of the satisfactory results, with absence of reactions, in 55 cases treated by this method.

LOCAL GOVERNMENT BOUNDARIES AND FUNCTIONS

The Local Government Boundary Commission have issued their report¹ for the year 1947, and if their recommendations are accepted by Parliament and the necessary legislation enacted there will be many changes not only in the boundaries between local authorities but also in their functions. It is stated in the report that after standing up successfully to the strain of total war and enemy attack the local government machine now has "the less spectacular but not less arduous work of dealing simultaneously and in circumstances of great difficulty with the immediate tasks of housing and of looking after the local welfare of a population which is re-sorting itself and turning over from war to peace, as well as all the problems involved in organizing and managing new systems of education, health, planning, fire services, the care of the young and the old, and many other services."

Since 1888 there has been no general review of the areas of counties, and of course the changes in the functions of local authorities since that date have been vast. There has been a constant struggle between the county boroughs and the counties, largely owing to the needs of the former for

Lebensraum at the expense of the latter. The counties have accused the county boroughs of going their own independent way without considering the wishes of the people who live outside the boundaries of the towns, and the county boroughs have reacted by making it plain that they consider the county councils interfering busybodies. Meanwhile the district councils—urban, rural, and non-county boroughs—have sadly watched their powers disappearing either to the central government or to the county and county borough councils. In fact, as the Boundary Commission imply, the inhabitants of some areas have been denied the use of public services such as main water and drainage because of the iron curtains which have been drawn along existing boundaries.

The recommendations of the Commission include some realistic compromises and appear to be both sensible and workable. It is proposed that there should be three units of local government—counties, county boroughs, and county districts. Excluding Greater London, the special problems of which still remain to be settled, there would be seventeen "one-tier" counties—large towns, or amalgamations of several towns such as the Potteries—which would be autonomous. The rest of England would be divided into forty-seven "two-tier" counties in which local government functions would be carried out partly by the county councils and partly by the county borough and district councils within the county. The new county boroughs, which would have populations of between 60,000 and 200,000, would be "most-purpose" authorities but not completely independent of the county councils. The distinctions between the present county district councils—namely, the non-county boroughs and the urban and rural districts—would be abolished.

If the Boundary Commission's proposals could have been carried through before the passing of the National Health Service Act the regionalization of the hospitals might have been planned differently, but in other respects the Commission's recommendations would not have a great effect on the pattern of the new health services. The main difference would be that the medical officers of health of some towns which are not now county boroughs and are under the yoke of a county council would be able to assume independence and plan local health and school medical services with responsibility only to their own councils.

It remains to be seen whether the central government will take the risk of bringing in a Bill to put the Boundary Commission's recommendations into effect. While there may be comparatively few people who feel strongly about the functions of local authorities, a great many will hotly contest the revision of town and county boundaries. Already M.P.s have been declaiming, "We do not want our town to become part of —shire," and doubtless the inhabitants of Rutland and other counties which may appear to be becoming uneasy. Worst of all, there is a hint in the Commission's report that a small part of Yorkshire might be transferred to one of the proposed new Lancashire counties. Civil wars have broken out for less.

YOU KNOW MY METHODS

The methods of medical diagnosis are akin to those employed by detectives on the scent of crime—at least by detectives in fiction, whose methods alone we have had the opportunity of studying. Our leading clinicians would surely approve of Sherlock Holmes's unflinching examination of minute detail—"It has long been an axiom of mine that the little things are infinitely the most

¹ Report of the Local Government Boundary Commission for the Year 1947. London: HMSO, 1947.

important¹¹—and his insistence upon the need for hard facts—"It is a capital mistake to theorize before one has facts."¹² That the medical man can learn much from Holmes's methods is only to be expected, for in relating to Conan Doyle was describing those of the famous Edinburgh surgeon, Joseph Bell, whose character inspired him to create Sherlock Holmes. Dr. Douglas Guthrie defended in these terms—if any defence before the medicalists were necessary—a delightful afternoon spent by the History of Medicine Section of the Royal Society of Medicine on April 7, when it held a symposium on "Conan Doyle and the Doctor and Detective Fiction."

Sir Arthur MacNalty opened the discussion with a biographical sketch of Conan Doyle, mentioning incidentally that his first medical publication was a letter to this journal,¹³ written two years before he graduated, on over-riding himself with gelsemium in order to determine the maximum safe dose. He drew attention to his curiously ambiguous attitude towards the Sherlock Holmes stories. Conan Doyle regarded them as being distinctly inferior to his historical works, and, becoming tired of his hero, tried to consign him to an honourable death in the last fight with Moriarty, but so great was the public clamour that he had to resuscitate him for a new series of stories. Two of the later speakers mentioned that friends of theirs had burst into tears on learning of Holmes's death. Unfortunately the reason for this deep attachment was not elaborated upon. No doubt our pleasure derives in the first place from the skill with which Holmes's character is delineated; and indeed his was a character that is peculiarly attractive to Englishmen, for he was the inspired amateur, the intellectual who played the violin quixotically, practised revolver-shooting in his flat, took cocaine, walked about in a dressing-gown, and above all adored men and society rather than books. Moreover, since the rise of Puritanism we have been rather a self-righteous people, and the pursuit and bringing to justice of the wayward and criminal in our society and in ourselves is an appealing prospect. Perhaps too our industrialized readers of detective fiction, reading of the doom that inevitably and with such ingenuity overtakes the criminal, obtain that catharsis that the Greeks experienced when watching their tragedy.

Mr. Zachary Cope, who eulogized Dr. Watson in a lightful Petrarchian sonnet, rightly pointed out what a loss it had been to medicine that Watson never described how he succeeded in weaning Holmes from his addiction to cocaine; nor indeed did he ever persuade Holmes to adopt tidier habits. In view of Holmes's distinctly Bohemian character it is not surprising that, as Dr. Guthrie said, Joseph Bell did not feel flattered by his close relation to this fictitious idol of the British public. The connexion was readily discernible, for the well-known sayings of Holmes were often originally the words of Bell. The surgeon, like many other great clinical teachers, would instantly impress on his students, of whom Conan Doyle is one, that they must never trust general impressions, and he would then stress the importance of trifles. Sir Robert Young in the discussion advocated the same view. "Every doctor is a detective." He taught his students, he said, by making them examine the patient and relate everything that they noticed.

Holmes's education was then discussed at some length, Dr. S. C. Roberts, an authority who has written a book on Dr. Watson, pointing out that so far as is known Holmes never went to school. Perhaps he had tutors; undoubtedly

he went to a university, probably Oxford or Cambridge, Oxford being the more likely. There is no evidence that he obtained a degree, nor even that he worked for one. He had read deeply on certain subjects—chemistry is mentioned—but he regarded detection as an art rather than as a science, and deduction as a form of artistic feeling. Clinicians might cautiously agree that that is true also of diagnosis. Nowadays, when the first thought of the newly qualified houseman is often to consider what laboratory tests he should order for his patient and in what order, he could do worse than learn the value of unaided intelligent observation, the patient collection of data, and deduction from sufficient evidence that Sherlock Holmes displayed to perfection.

GOLDEN JUBILEE OF THE R.A.M.C.

Just over fifty years ago a deputation from the British Medical Association¹ waited upon the Marquis of Lansdowne, the Secretary of State for War, to lay before him the views of the medical profession on the condition of the Army Medical Services and the need for certain reforms. It appears that the deputation was welcomed² and assured that the Secretary of State was entirely with them in regarding with very serious concern the problems raised. Lord Lansdowne said that the most important suggestion³ that had been put forward by the deputation was the one proposing the formation of a medical corps, which it was thought should be created by the consolidation of the Army Medical Staff and the Medical Staff Corps. Only a few months later it was announced that this change had been brought about and that Her Majesty had been pleased to signify her intention of bestowing the title "Royal" upon the new Army Medical Corps.⁴

The Royal Warrant of Queen Victoria was dated June 23, 1898, and at the same time the familiar badge with the motto *In arduis fidelis* was designed and dull-cherry facings appeared on the uniforms of all ranks, the same colour replacing scarlet for the piping on tunics and for trouser welts. Later in the same year the Corps made its first formal appearance in the field as part of the Nile Expeditionary Force of 1898. The history of the Corps in the 1914-18 war is well known, and its achievements in recent years evoked world-wide admiration.

The Golden Jubilee of the Corps will be fittingly celebrated on June 23. Her Majesty the Queen, who is Colonel-in-Chief, has graciously expressed her intention of visiting the depot and training establishment at Crookham on that date. There will also be celebrations of a different kind in other parts of the country. In London a Jubilee Rally will be held in the Central Hall, Westminster, when short addresses will be given by Sir Alfred Webb-Johnson, P.R.C.S., General Sir James Steele, the Adjutant General, and General Sir William Slim. On this occasion the Corps Band and Bugles will introduce a new regimental march to the public.

General Sir Alexander Hood, whose retirement as Director General of Army Medical Services was announced only recently,⁵ informs us that a most cordial welcome will be extended at the celebrations to all who have served with the Corps during the last fifty years, and also to the sister medical services in the Royal Navy and Royal Air Force. Further particulars may be obtained from the Hon. Secretary, R.A.M.C. Association, at 84, Eccleston Square, London, S.W.1.

B.M.A. QUESTIONARY TO MINISTER

1. The Minister stated in the House of Commons that the Government proposed to make it impossible to institute a full-time salaried service by regulation alone. The profession welcomed that statement. Would the Minister indicate how it is proposed to do this; first, in relation to general practitioners, and, secondly, in relation to hospital staffs?

2. As this proposed step in its relation to hospital staffs would appear to involve a policy of keeping whole-time consultant and specialist appointments to a minimum would the Minister agree to preserve, to the extent to which the public desires it, existing private accommodation as such so as to make possible the continuance of the part-time system of consultant and specialist staffing of hospitals?

3. Would the Minister state what assurances exist or can be given that hospitals or similar establishments not taken over on the appointed day or later established privately will not subsequently be the subject of compulsory purchase under the Act?

4. Does the Minister agree that it should be required that in relation to every hospital there should be a medical committee; that such medical committees should be represented by their own nominees on Boards of Governors or Hospital Management Committees, enjoying the full status of membership of such bodies; that in the case of teaching hospitals the medical committee should be representative of all consultants and specialists on the staff, teachers and non-teachers?

5. Will the Minister extend his assurance on the subject of freedom of speech and publication within the new Service to include not only such freedom on professional and scientific matters but also the right of criticism on matters of administration?

6. Would the Minister state what security in relation to their hospital appointments will be enjoyed by existing members of hospital staffs at the time of taking over and by hospital staffs subsequently? Does the Minister contemplate the establishment of machinery for the investigation of complaints, including the right of appeal against any decision of the Board of Governors or Regional Hospitals Board?

7. Will the Minister indicate his view on the second resolution of the Royal College of Physicians, viz.:

"A principal cause of the present discontent with the National Health Service is the power possessed by the Minister of Health to change its character by regulations. The College therefore suggests that an amending Bill should be introduced, to make regulations affecting the National Health Service subject to special procedure."

8. The Committee, while welcoming the abandonment of the universal basic salary, submits to the Minister the following points for consideration:

It is accepted that there are circumstances in which some practitioners need regular annual payments of the kind suggested; the amount of such payments will vary with different practitioners according to the circumstances under which they work. In some cases such annual payments should be for a period, in others permanent. The Committee suggests that the object the Minister has in mind of enabling practitioners needed in an area to practise there will be served more efficiently and economically if such payments are made on the recommendation of the Local Executive Council according to the circumstances of each case. In this way such payments will not be made to practitioners who do not need them, and where they are made they will be related to the actual needs revealed by the individual case. Will the Minister accept this modification of his own proposal?

9. The profession is anxious to co-operate with the Minister in remedying any defects which may exist in the distribution of general practitioners in relation to the needs of the population. Their representatives have argued that the introduction of a service available to all will of itself go a long way towards the solution of any problems which may exist, any residual problem being met by the Minister's power to appoint practitioners to under-doctored areas. The Minister has agreed that there are likely to be few areas where the question of consent to new participants in the Service will arise. Bearing in mind the profession's dislike of the proposed limitation of movement, coupled with its desire to solve any existing problem of distribution, it is suggested that the introduction of the scheme

laid down in the Act should be postponed for an agreed period in order that it may be determined by experience whether the problem does in fact largely solve itself or whether the operation of the provisions of the Act in this respect is necessary. During such period the profession will gladly establish an advisory machinery to keep practitioners informed of available appointments and opportunities. Will the Minister agree to such a deferment?

10. Would the Minister agree to request the Lord Chancellor to appoint a High Court Judge to the Chairmanship of the Tribunal?

11. The profession urges the preservation of the ownership of goodwill in general practice because of the essential professional freedoms which it safeguards. Will the Minister indicate how, with the abolition of that ownership, these freedoms will be preserved and in particular

(a) freedom to choose the area of practice and one's medical colleagues, partners, and assistants;

(b) freedom to allocate duties and responsibilities within a partnership or group;

(c) freedom to decide when an additional partner or assistant is necessary;

(d) a say in the choice of a successor?

12. Will the Minister explain why it is necessary to limit the practice of midwifery to practitioners with special qualifications under the English Act, whereas no such limitation is thought necessary in the Acts for Scotland and Northern Ireland?

13. Will the Minister give an assurance that practitioners not in the new Service will be able to obtain for their patients, as benefits under the Service, such consultant and specialist including diagnostic, help as they may deem to be necessary?

14. Does the Minister agree that the appointment of members of the medical profession to administrative and other bodies should be in consultation and agreement with the representative bodies of the profession?

[For convenience "the Minister" is used to include the Minister of Health and the Secretary of State for Scotland.]

MR. BEVAN REPLIES

The Minister and the Secretary of State for Scotland have considered the fourteen questions which the British Medical Association sent to them on April 8 and which were discussed with representatives of the Association on April 12. A summary of their replies is set out below.

1. There has not yet been time to work out the actual wording of the new measure, and when he does so the Minister will welcome the help of the profession.

For general practitioners the proposed effect of the new provision will be that they are paid entirely by capitation fee, except for the new practitioner in his opening three years and any other practitioner who himself opts to have a fixed annual element in his salary with the rest on a capitation basis. The question of conditions under which that option should be exercisable is mentioned under question 8 below.

As to hospital staffs, there seems to be some misunderstanding. The "regulation versus statute" issue does not arise in the same way in their case; nor does that of "capitation versus salary or sessional fee." Hospital appointments (usually part-time for specialist staff) will be offered, by advertisement or otherwise, in the ordinary way, and people will accept them or not as they choose; there is no kind of compulsion nor any power of compulsory transfer to other areas or hospitals. If any regulations are made under Section 66 of the Act the Minister will exclude from them any provision for universal whole-time specialist services. Appointments of specialist staff will rest with Regional Boards and the Boards of Governors of Teaching Hospitals, and there will be special professional advisory machinery for advising on the suitability of applicants—in the manner often previously explained. (As to existing staff, see 6 below.)

2. It has always been anticipated that consultant and specialist appointments should in most cases be part-time, and—where appropriate—at more than one hospital. They are essentially

regional and not a local Management Committee affair. As private pay-bed accommodation, this has been promised for the scheme and is expressly provided for in the Act. It is to be assumed that at the outset of the scheme it will lie where it is at present, but obviously the Minister cannot tie himself or the future hospital bodies to an exact future distribution now. The main point is that the continuance of private specialists at hospitals accords with the intention of the scheme, and there will therefore be facilities for them.

1. For obvious reasons the Minister could not give such an assurance. A particular building might become essential to a new Service, and that applies to any building (whether at present used for medical purposes or not). But the acquisition by purchase of, say, nursing homes or excluded hospitals is in prospect. The exclusion by the Minister of 200 hospitals entirely, indeed, is direct evidence to the contrary, and he would rarely exclude a hospital first and then acquire it by purchase afterwards (and, once excluded, it could only be acquired by purchase).

if any private concern were later to contemplate spending money on a private hospital or home run for profit, and feared that the Minister would wait for it to be there and then use compulsory purchase powers on it, obviously the sensible course would be first to discuss the project with the Minister at the time, and the Department ought certainly to be ready to indicate its likely attitude straight away. The private concern would then know where it was.

4. The Minister entirely agrees with the system of medical committees in hospitals. But he could not compel medical staffs to set them up (nor would the Association presumably wish him to try!). He has already included in his guidance Regional Boards and Hospital Management Committees a declaration of the importance which he attaches to the system and asked that every encouragement and facility should be given to it. He also agrees that in teaching hospitals such committees should be representative of all consultants and specialists on the staff, whether they are teachers or not.

As to the representation of medical committees on Boards of Governors or Hospital Management Committees, the Minister follows the Act, which requires the latter bodies to include persons appointed after consultation with the senior medical staff of the hospital or hospitals, and the former bodies to include up to one-fifth of their members nominated by the medical and dental teaching staff. In practice, of course, this means that both bodies will include members of the medical committees, with full membership. Moreover, the Minister plainly thinks that consultation should include consultation with the medical committee, where there is one.

5. The assurances already given cover complete freedom to publish views on the organization and administration of the Service, as well as on clinical matters, without obtaining any prior consent to do so.

6. In practice on the appointed day the existing staffs of hospitals will be taken over by the Regional Hospital Boards. Hereafter it will be the duty of the Boards to review the specialist services of their regions, and they will offer new appointments to their staffs either in their existing or other hospitals, which they will be free to accept or refuse as they like (see also question 1).

As to the latter part of the question, medical staffs of hospitals will be in the same general position in these respects as they are now. They will have all normal remedies for unlawful termination of any engagement, and in addition their medical committees and a Whitley machinery to help protect their interests. It will be a proper function of the Whitley organization to devise machinery for the ventilation of complaints and grievances.

7. It is not clear what is meant by this resolution, which does not explain—for instance—what "special procedure" it has in mind. Already all regulations have to be examined by a special committee in Parliament to decide whether they go beyond the scope of the Act under which they are made or whether there is any feature of them so unusual or important that the special attention of Members should be drawn to it. Any main cause of apprehension about regulations under the Act has been removed by the undertaking to remove a full-

time salaried general practitioner service from their scope. For the rest of their purposes under the Act, it seems to the Minister that regulations have advantages which the Association is overlooking. For example, it could only be detrimental to the doctors' interests if, every time some increase in capitation fee (as recently under the old Act) became desirable owing to changing conditions, it depended on finding Parliamentary time for a new Act to give effect to it. The use of regulations for things which require frequent flexibility has been familiar under the old National Health Insurance Acts for about 36 years, and has not—the Minister believes—been found anything but advantageous to the doctor.

8. The local Executive Council will certainly be consulted on the need for any variations of additional fixed annual payments to meet the needs of doctors practising in different areas.

The Minister understands, from the discussion on April 12, that what is in mind is that there will be various kinds of case where a doctor could—by taking the £300 system—profit financially himself from the equivalent of a higher rate of remuneration per patient at the expense of other doctors. The Association feel that while this is justified wherever there is need in the individual case, there will be other cases where there is no such need and where the results might be unfair—and that therefore there should be some other check on the decision than the unrestricted opting of the doctor. Within the scope of his recent declaration in the House of Commons the Minister is perfectly willing to discuss with the profession all the details of the conditions and methods through which opting will be conducted.

9. The Minister cannot agree to this further alteration of the Act, which would in any case be administratively difficult at a time when the settlement of succession to practices by sale and purchase is ceasing. The more reasonable course seems to be a review of the working of the system after an agreed period, during which it can be seen if it is as irksome as the Association seem to anticipate. The Minister is quite prepared to agree that there shall be a special review of the usefulness of this feature of the Act in, say, two years' time.

10. The Minister has already given an assurance that the chairman of the Tribunal shall be a lawyer of high standing, appointed by the Lord Chancellor. He cannot agree to stipulate that he shall be a High Court Judge. For one thing, it is too restrictive: it might well be very difficult to be sure of being able to secure the services of a Judge at any particular time. For another, a Judge, so appointed, would not be acting as a Judge when conducting the Tribunal—but simply as a lawyer of high standing, which the Minister has already promised.

11. The answers, point by point, are as follows:

(a) Every doctor will be free to practise where he chooses, unless it is one of the areas where the Medical Practices Committee decide no more doctors are needed in the Service. In all cases except the latter, "consent" will be automatic. Similarly, all will be free to choose colleagues, partners, and assistants unless the area requires no more (as above) or the regulations on the employment of assistants* are contravened. Where more than one doctor wishes to be the partner or assistant in question the Medical Practices Committee will be asked to observe the wishes of the doctors concerned.

(b) Partnerships and groups will be entirely free to allocate duties and responsibilities, as now.

(c) Doctors will be free to decide when an additional partner or assistant is necessary, subject to the cases where the Medical Practices Committee decide that no additional doctor at all is needed in the area and subject to the conditions about assistants.*

(d) A retiring doctor's views as to his successor would be taken into account by the local Executive Council, but that Council must ultimately decide what to advise the Medical Practices Committee about the new practitioner to come to the area.

12. The term "special qualifications" does not mean any special degree or diploma but simply inclusion in a list of general practitioner obstetricians compiled locally by a professional body, in accordance with the recommendation of a committee on maternal care established by agreement with the Negotiating Committee.

* The regulations about assistants require the agreement of the Executive Council to the employment of an assistant for more than 3 months. This is on the lines already familiar for the last 36 years.

General practitioner obstetricians will undertake, among other duties, to answer midwives' calls for medical aid and will be entitled to special fees.

Circumstances and practice are entirely different in Scotland.

13. Yes, within the available resources of the scheme.

14. This was settled when the Act was a Bill in Parliament in 1946. The Minister has to consult, but constitutionally the decision has then to be his. But naturally he would want to take those whose names are agreeable to the bodies consulted.

In conclusion the Minister said that the statement which he made in the House of Commons on April 7, together with the assurances which he had given to-day, represented in the Government's view the most reasonable modification of the scheme which was practicable to enable the Service to start, with the other social legislation of the Government, on July 5 next. It was, of course, their wish—as and when shortcomings were found in the scheme's working—to correct these as soon as possible, and they would do so. The Minister would always want to hear the views of the profession on any aspect of the working of the scheme. But the principal thing now was for a start to be made and experience gained.

The Minister hoped that, in view of the short period remaining, he would now have the immediate help of the profession in any consultations which he had initiated, or might initiate, with them.

AMERICAN CONGRESS OF INDUSTRIAL HEALTH VIEWS ON STATE MEDICINE

thousand delegates attended a four-day conference on industrial health sponsored by the American Medical Association. The conference, which was held at Cleveland, ended on Jan. 8.

A certain amount of publicity has been given in the American press to the widely differing views of some of the guest speakers at this conference. Speaking on the opening day Mr. Max Meyer, of New York, chairman of the Board of the Fashion Institute of Technology and Design, painted a glowing picture of the improved health and welfare conditions of workers in the garment trade. He attributed this solely to the efforts of men in industry, and added: "None of the responsible groups now advocating compulsory health insurance are advocates of State medicine."

Two days later Clinton P. Anderson, Secretary of Agriculture, produced a series of depressing facts and figures to demonstrate how poor the medical care of the rural American still is. He said that at the present rate of development of local public health units it was estimated that it would take more than one hundred years to cover the whole country, and went on to say: "Typhoid claims three times as many rural as urban victims and diphtheria twice as many. The infant mortality rate is one-fourth higher and the maternal rate a third higher. During the second world war farmers as an occupational group had a rejection rate of 53.4%, as compared with an overall rate of only 43%." He also said that prepayment plans for surgical and medical services offered by State and county medical societies had reached less than 1% of rural people.

Town and Country

There exists in America to an extent undreamed of in a country of Britain's size a basic split between towns and rural areas—between the country hick and the city slicker. Mr. Anderson's report is one of many that show that, at present, the hick is having a very rough deal in the matter of medical attention. American practitioners are reluctant to leave the cities for a country practice where therapeutic facilities are poor and payment is small, or in kind, or even non-existent. The first factor is probably more responsible than the second for this disinclination. American clinical teachers stress the value of laboratory tests in diagnosis to such a degree that their pupils feel it impossible to make a diagnosis based purely on a history and physical examination.

Mr. Meyer's description of health conditions in the clothing trade is perfectly correct and, in fact, might be that of any American industry. His dislike of State medicine is also shared by the larger proportion of the country's industrialists who rather than see the institution of a socialist measure, are prepared to pay all or part of their employees' subscriptions to private health insurance schemes. On the other hand, Mr. Meyer's statement on the reaction of "responsible" groups to State medicine must be taken with a grain of salt. Many Americans feel that voluntary health insurance can only operate in industrial areas, and then only in times of industrial prosperity and full employment. In fact only two days after Mr. Meyer's pronouncement President Truman, in his "State of the Union" address to Congress, said: "The fact is, however, that most of our people cannot afford to pay for the care that they need. I have often and strongly urged that this condition demands a national health programme. The heart of the programme must be a national system of payment for medical care based on well-tried insurance principles."

President Truman's views may not coincide with those of all Democrats, and they certainly coincide with those of very few Republicans. Nevertheless, there may come a time in the next decade or so when a Democratic President will be backed by a Democratic Congress. If by that time the advocates of voluntary insurance have not produced an efficient overall scheme it seems possible that America will join the ranks of those nations which possess a National Health Service.

Reports of Societies

PRIMARY TREATMENT OF VARICOSE VEINS

At a meeting of the Section of Surgery of the Royal Society of Medicine on April 7, with Mr. E. F. FINCH in the chair, the subject for discussion was the primary treatment of varicose veins.

Mr. DICKSON WRIGHT repeated Charles Mayo's remark that varicose veins, along with pruritus ani and some other intractable complaints, made up the "dust-heap of surgery." They had long been the despair of surgeons. With the loss of "face" which came about owing to recurrences as the years went by the operations proposed seemed to grow in ferocity. One German surgeon even went to the extent of cutting the skin spiral-wise from the knee to the ankle, leaving the resulting wound to heal by granulation. The healed legs resembled those of a Chippendale table. Another vicious method was to circumscribe the skin of the leg just below the knee down to the deep fascia, so that every superficial vein was divided. This did not help the varicose veins and sometimes ended in amputation from contraction of the scar. Others carried out laborious and extensive dissection of the veins, but the results were poor. Mayo invented a ring stripper to strip out lengths of vein, and Babcock a long probe to pass down and avulse the vein.

The injection treatment, first thought of by Pravaz and elaborated by Sicard and Forrester, provided an escape from the disappointing surgery of the day, and seemed to be a way out of the difficulty, but after an enthusiastic start the results proved disappointing on account of recurrences. An attempt was made to diminish recanalization by using different sclerosing agents, but although some were better than others the treatment proved inadequate except for the lesser cases. The cases which occurred most persistently were those in which a free communication could be demonstrated between the superficial and the deep veins. Once these valves became incompetent the veins were subject to greatly increased intravenous pressure, which would be greatly helped.

Mr. Dickson Wright proceeded to show a cinematograph film to illustrate the ligaturing of the sapheno-femoral junction—a simple operation, but one in which care was necessary because accidents such as tearing of the vein might occur. Accurate diagnosis should be made of the degree of involvement of the three venous systems—the internal and external saphenous and the gluteal. Mr. Wright stressed the need for adapting the procedure to the individual case, and the three-

cel film showed various modifications and adaptations. A case as shown which had been treated by bandaging only, and the treatment of which could have been shortened if the obviously incompetent vein had been ligated. Trendelenburg's operation was ineffective because the ligature was not made at the sapheno-femoral junction and important tributaries were left above the ligature.

After describing the details of the technique Mr. Dickson Wright added one or two points about the dangers of the ligation operation. The femoral vein might be tied in error; in such a case not much good was done, but not as much harm as might be imagined. Again, infection might occur after these wounds, but as chemotherapy was available this was not as serious a sequel as in the past. If pulmonary embolism should occur the femoral vein should be tied and the patient put on anti-coagulants. Rest in bed should be avoided as much as possible on account of the possibility of femoral thrombosis and embolism. Extensive cases were now given a general anaesthetic—thiopentone—and a large quantity (100 ml.) of a 30% saline solution was distributed in various parts of the venous system; it was hoped thereby to knock out all the affected veins in one assault. The danger of recurrence must be greatly diminished if no varicose veins at all were left as a starting-point. Contraindications to the operation were old age, obesity, and diabetes, and if the patient had a history, family or personal, of easily provoked phlebitis it was wise to abstain.

Venogram Studies

Mr. J. B. KINMONTH described the treatment of varicose veins in the light of information derived from about 100 venograms and histological studies. He referred particularly to retrograde injections at operation, which were intended to obliterate the great saphenous vein. This appeared to be an inefficient method because much of the dye was shown to go into the deep veins; very little of the injected fluid stayed in the great saphenous veins and very little went below the knee. It tended to pass into the communicating veins or the normal veins. Serial venograms after injections made into the leg showed that the optimum amount in a single injection was 1 to 1.5 ml.; larger amounts tended to spill over into the deep veins. Serial pictures also showed that fluid passing into the deep veins stayed there longer than might be expected, stayed for a longer time still in the communicating veins, and could be seen to linger in the neighbourhood of the valves—a very significant observation.

More severe cases with incompetent great saphenous valves required operation. He recommended high sapheno-femoral ligation, probably combined with ligation at knee level or at the thigh, no retrograde injection, but local injection of the calf varicosities if necessary at a later date. In a mild case injection should be practised, using the empty vein technique, with the knee horizontal. Not more than 1 to 1.5 ml. should be given at each injection, and the leg should be kept still for five minutes, after which the patient should be instructed to walk about briskly.

Prof. A. M. BOYD said that the treatment of varicose veins had been the subject of acrimonious discussion ever since Hippocrates. Treatments had been discarded and reintroduced repeatedly. The reason for the unsatisfactory results lay in the aetiology of varicose veins. He believed that varicose veins were primarily due to a congenital deficiency or weakness of the valves and communicating veins. The condition was therefore progressive and no single operation was likely to cure it. Any treatment of varicose veins was a severe assault on the circulation, perhaps more severe than was imagined. Superficial veins were very liberally supplied with nerve-endings and arteriovenous anastomoses in their walls. One of the indications for treatment was, of course, pain, but he was doubtful about varicose veins causing pain, though it was true that the posterior saphenous group did so. He thought that in some cases the cause of pain was a deep phlebitis.

The sheet-anchor of treatment was adequate ligation. He had tried to prove whether a sclerosing agent would get into the deep veins or stay there, and after some trouble in getting a suitable radio-opaque solution he was able to show that the

sclerosing solution would go into the deep veins, and, what was worse, would remain on the valves. He was prepared to believe that if only a small quantity were used—say 2 or 3 ml.—comparatively little got into the deep veins and only small damage was done, but the procedure was not without danger. Below the knee it was probably safe, though now and then people were found with fairly large communications just below the head of the tibia. Bearing in mind that varicose veins were rather a doubtful cause of symptoms, and that what one was out to do was to prevent chronic venous insufficiency and ulceration, more and better ligation was probably safer than attempting by other means to produce a cosmetic result.

In some further discussion Dr. MARTIN asked what kind of supporting bandages were recommended for a varicose ulcer. Mr. SOLLY COHEN said that patients who developed embolus did so not on account of the little stump left behind in the ligation but because of the solution which flowed into the deep vein causing a clot. Mr. DICKSON WRIGHT said that he was a great believer in elastoplast in the treatment of varicose ulcers. It should be reinforced by strips of adhesive across the ulcer and after that by some felt or rubber, and the elastoplast was placed, as a rule, above that, giving a very firm support.

OPHTHALMOLOGICAL CONGRESS

Subjective Disorders of Vision

The annual congress of the Ophthalmological Society of the United Kingdom was held in London from April 8 to 10, under the presidency of Dr. A. J. BALLANTYNE (Glasgow). Prof. MARC AMSLER (Lausanne) delivered the Bowman Lecture on "The Vegetative Eye"; Prof. W. H. MELANOWSKI (Warsaw) contributed a paper in which he urged that atropine was indispensable in starting the treatment of glaucomatous iridocyclitis, and other distinguished foreign guests who joined in the various discussions included Prof. H. J. M. WEVE (Utrecht), Prof. VAN DER HOEVE (Leiden), Dr. ELES (Copenhagen), Dr. J. W. NORDENSEN (Stockholm), Dr. THOMASSEN (Oslo), and Prof. FRANCESCHETTI (Geneva).

Medical Aspects of Disorders of Vision

The principal discussion, on subjective disorders of vision, excluding those due to local ocular disease, was opened from the standpoint of general medicine by Prof. HENRY COHEN. In the process of seeing, he said, two chains of events were concerned. The first began with the entry of light into the eye, traversing its transparent media to the receptive retinal nerve endings, whence impulses spread along well-recognized nerve pathways to excite ocular muscle movements and electrical disturbances in the brain cortex. The second comprised that still incomprehensible series of events which translated these cortical disturbances into the mental process of "seeing." Disease in either of these chains would affect vision. Such visual disturbances might arise from hereditary developmental defects, infection, nutritional abnormalities, toxæmias, vascular disturbances, degenerative lesions, and neoplastic changes.

The first major subjective disorder of vision which came to the general physician, Prof. Cohen continued, was visual fatigue, common in patients suffering from exhaustion of all types. Complaint was made sometimes of blurred distant vision, a useful sign in the differentiation of hypoglycaemic and hyperglycaemic states. Blurred near vision was not infrequently associated with diabetes mellitus, not because of the hyperglycaemia, but rather because of the associated dehydration. Patients with continued vomiting or marked diarrhoea, patients with diabetes insipidus and excessive water output, would commonly complain of blurred near vision; 15% of patients under 21 suffering from diabetes showed marked blurring.

Of visual hallucinations very little was known. No one had as yet with certainty produced a visual hallucination by direct stimulation of the cortex, yet in diseases of the cortex hallucinations occurred. Hallucinations were associated with many toxæmias. Digitalis would commonly lead to marked chromatic disturbance, frequently "white vision," in which all objects appeared to be covered with snow, but sometimes green,

or he had even seen blue, vision. Unilateral sudden blindness almost invariably had a vascular basis, while bilateral sudden blindness was usually of toxic origin. Colour blindness rarely came within the purview of the general physician. He added a word on the sudden "black-outs" which were not primarily visual disturbances but were apparently psychical in origin, such as the transient interruptions of consciousness which might occur in epilepsy. Not infrequently patients with petit mal consulted the ophthalmologist because of transient loss of vision.

Ophthalmological and Neurological Aspects

Mr. J. H. DOGGART classified subjective disorders of vision in three grades: (1) the obtrusive symptom, such as visual failure, which sent the patient rushing for medical relief; (2) the kind of sensations which could be pieced together only by expert questioning; (3) the subjective disorders, such as small field defects, which were brought out only by special tests. The same kind of symptom might be fitted to any of the categories, and its effective severity would vary with the patient's tolerance and powers of observation. One victim might be incapacitated by a paracentral scotoma, while another might fail to realize until questioned that he had been vaguely aware of it for some time, and yet another might continue in ignorance until the scotoma had been mapped out by charting the central field.

Diplopia, said Mr. Doggart, did not necessarily indicate ocular paresis. There might, for example, be a convergence defect associated with an anxiety state in a patient whose internal reactive function was normal in all conjunctive movements. When a patient did not complain of diplopia on his own initiative it was unwise to ask whether he had seen double. The over-analytical patient might proceed to give an account of what was nothing but a physiological or, as it had been called, an "introspective" diplopia. Defective vision suddenly arising in one eye, followed by substantial recovery within two or three weeks, was a well-known early manifestation of disseminated sclerosis. A similar lesion implicating both optic nerves behind the globes might occasion transient disturbance of vision in certain cases of pituitary or other intracranial neoplasms. Hallucinations opened up a fascinating subject. The laic man was quite convinced that he could not mix fantasy with objective events, yet the arguments against a sharp dividing line were formidable. Tricks could be played by the memory, however recent the event, as those accustomed to hear evidence given in court well knew. And at what point did legitimate clinical optimism degenerate into "facultative Nelsonism" by which latter device the surgeon could direct a blind eye on his failures and claim 100% success? He reminded his hearers of the visual aura of epilepsy, the geometrical figures which emerged at the height of a migrainous attack, and the strange images which might haunt the victims of Ménière's disease. The most elaborate hallucinations sprang from damage to the visual cortex, whether vascular, inflammatory, toxic, or traumatic.

Dr. DENIS WILLIAMS said that ophthalmologists and neurologists, as a result of their precise methods of testing visual function, were inclined to consider perception as tested in terms only of the lower visual pathways. He gave some curious examples of persons who had lost at least one-half of their total visual pathway and yet were able to "spare" or "split" their macular vision at will. Observations on the nature of macular "sparing" illustrated the effects of other related mechanisms upon the results of simple visual testing.

Dr. H. M. TRAQUAIR said that he had always been in the habit of teaching students that the eye was like a telephone receiver, with no function at all save to accept images and translate them into messages which were sent to an exchange, possibly in the area striata, and that the act of "seeing" was performed not by the eye or its connexions but by the ego. A discussion in which many strange cases of disorientation and hallucination were mentioned was contributed to by Mr. R. LINDSAY-REID, Mr. D. V. GILL, Mr. EUGENE WOLFF, Mr. F. RILEY, and others.

Detachment of the Retina

Mr. C. DEE SHAPLAND read a paper on prognosis in detachment of the retina. He reviewed 155 cases (122 civilian and

33 Service) operated upon by diathermy. About two-thirds of the cases were in males. In this and other series a slight but constant tendency for the right eye to be affected rather than the left was noted. In the civilian cases a successful result in the sense of reposition continuing after twelve months was obtained in 55.8%, and in the Service cases—a younger and selected group—in 80%. Mr. Shapland said that the results were weighted in favour of the surgeon and the patient up to the age of 50, but after 50 it was the other way about, although the oldest patient in his series—a woman of 78—showed a good result.

Prof. WEVE (Utrecht) said that his department had statistics concerning 3,000 cases operated on during the last thirty years. The cases which healed quickly and well were almost always those which were dealt with immediately. He was astonished at the number of ophthalmologists who, seeing a case of haemorrhage in the vitreous, never supposed it to be the beginning of a detachment and put the patient on the waiting list.

Mr. G. T. W. CASHELL described two cases of special interest: the first a subconjunctival rupture of the globe due to penetration by a cow's horn, and the second an aneurysmal varix of the retina. The first case showed an extensive migration of uveal pigment. Dr. W. C. SOUTER mentioned that in Aberdeenshire he had found cows responsible for sclerectomy, iridectomy, subconjunctival dislocation of the lens, total dislocation of the lens, and enucleation of the globe.

Retinal Vascular System

Dr. I. C. MICHAELSON described some research on the mode of development of the vascular system of the retina. He said that a study of the developing retina of man and other mammals had shown that vessel growth in the retina was by a process of budding from pre-existing vessels. The formation of retinal capillaries was pre-eminently a function of the retinal veins. If vein and artery were close together, growth took place initially from the side of the vein remote from the neighbouring artery. The spread of capillary growth towards an artery extended for only a certain distance, leaving finally in the definitive eye a well-marked capillary-free space around the arteries. This suggested that a factor affecting the growth of retinal blood vessels was present in the extravascular tissue of the retina and in such concentration that it differed in arterial and venous neighbourhoods, its action being predominantly on the endothelium of the veins. If the bulk of the capillary system in the retina could be considered as part of the venous system, and the arterial system as supra-capillary, such dispositions had implications for the appreciation of diabetic and hypertensive retinopathy. In the former capillary disturbance was evidenced by micro-aneurysms, haemorrhages, and exudates closely associated in time with changes in the visible veins, and in the latter long-continued arterial or arteriolar changes might be present without evidence of capillary disturbance. Development showed a dividing line in the vascular system corresponding to that found in pathological processes.

A paper on "Latent Nystagmus" was presented by Mr. T. KEITH LYLE. He said that this condition was first described in 1872, and cases had been recorded by several observers, but in many such cases there had also been signs of organic disease in one or other eye, conditions which might of themselves give rise to nystagmus. In the cases he reported there was no sign of organic abnormality in either eye. He showed a film of two cases in small girls taken eight years ago, and a similar film of the same subjects taken recently.

Glaucomatous Eyes

Dr. T. L. THOMASSEN (Norway) read a paper on venous pressure in glaucomatous eyes. He showed that venous pressure, compared with bulbar pressure, is high when the ocular pressure is in an increasing phase and low when the ocular pressure is in a decreasing phase. After the instillation of pilocarpine the venous pressure falls first and the ocular pressure shortly afterwards.

Mr. J. P. F. LLOYD surveyed 45 cases of congestive glaucoma, the average time of the congestive attack being eleven days.

He wondered whether operation was justified when the eye had settled down after what might be the only crisis in a lifetime. Dr. G. I. SCOTT described the use of the Bjerrum screen in the early diagnosis and prognosis of chronic glaucoma simplex.

Prof. ARNOLD SORSBY presented a classification of unassociated dystrophies of the fundus, discussing the topographical types, varieties of reactions, and genetic behaviour. In this connexion Prof. FRANCESCHETTI (Geneva) mentioned the remarkable familial incidence of choroiditis in certain valleys of Italian Switzerland. Other papers were by Dr. HELEN DIMSDALE and Mr. D. G. PHILLIPS on ocular palsies due to infection of nasal sinuses, Mr. EUGENE WOLFF on the conjunctival naevus, and Mr. A. G. CROSS on papilloedema in association with toxic hydrocephalus. Pictorial demonstrations were given by Dr. H. M. TRAQUIR and Dr. J. ELLISON, and Dr. W. C. SOUTER showed a colour film of a man who had the power of everting completely one or both upper eyelids without assistance, though he did it more surely with finger pressure on the temples. The film showed the great elasticity of his facial muscles. Another event of the Congress was a clinical meeting at the Ophthalmic Institute, Central London Ophthalmic Hospital, Judd Street, when about twenty cases were shown.

STREPTOMYCIN

At a meeting of the Liverpool Medical Institution on Feb. 19, with the president, Prof. T. P. McMURRAY in the chair, Prof. NORMAN B. CAPON opened a symposium on streptomycin.

Prof. Capon outlined the events leading up to the beginning of streptomycin trials, on behalf of the Medical Research Council, at Alder Hey Children's Hospital in February, 1947. He emphasized that treatment with streptomycin was a severe trial for the patient even though toxic effects were few, and it imposed a strain upon both medical and nursing staffs. It was clear that the prevention of spread of the disease to children and adequate provision for the care of cases of primary tuberculosis were still the most important aspects of the problem.

Dr. ROBERT HUGHES described the organization of a centre for the streptomycin treatment of tuberculous meningitis and miliary tuberculosis at the Royal Southern Hospital, Fazakerley, in September, 1947. So far 10 cases had been seen, and 5 of them had completed the course of treatment. Of these patients, one—a case of miliary tuberculosis with meningitis—had apparently been cured completely and was now perfectly well. The results in the other four cases of meningitis were unsatisfactory in varying degrees. In view of the results at Alder Hey Children's Hospital he suggested that there might be more than one type of tuberculous meningitis and that those cases associated with miliary tuberculosis might be more amenable to streptomycin than those with meningitis due to rupture of a tuberculoma. The cases treated were described in some detail. Toxic reactions to the drug had been almost invariably mild and had necessitated cessation of the treatment in one case only.

Dr. Hughes concluded by saying that streptomycin as used at present was not the complete answer to these problems. Perhaps it might be used more successfully in conjunction with other forms of chemotherapy. At the present time, too, there was not a sufficient quantity of the drug nor enough beds or staff to treat all the cases of these conditions which occurred.

Method of Treatment

Dr. R. M. TOPP said that during the past twelve months 29 cases of various forms of tuberculosis were treated with streptomycin at Alder Hey Children's Hospital. The drug was given intramuscularly in doses of 0.02 g. per pound (454 g.) body weight per day in divided doses six-hourly; and also in the cases of meningitis intrathecal doses of 0.1 g. were also given daily. Intramuscular therapy was continued for an average of twelve weeks in patients who had had over four weeks' treatment. Intrathecal injections were originally continued for long periods, but experience had shown that one or two short courses of seven days' duration with an interval of fourteen days between the courses produced better results.

Four cases of miliary tuberculosis were treated and two survived; one patient was alive and well forty weeks after the onset of the disease. Four cases of tuberculous bronchopneumonia all survived and three were alive fourteen, twenty-two, and forty-six weeks after the onset of the illness. Twenty-one cases of tuberculous meningitis—with or without evidence of miliary tuberculosis or tuberculous bronchopneumonia—had been treated and seven were alive. Three of these had completed streptomycin therapy and had survived nineteen, twenty-three, and forty-six weeks after the onset of the disease. Clinically they showed no evidence of meningitis, but one patient was completely deaf. A raised protein and increased cell count were still present in the cerebrospinal fluid. These three cases had been examined by a psychiatrist, who reported that none of the children showed any evidence of moral deterioration, change of disposition, anxiety, moroseness or apathy, but in the deaf child there was some slowing of mental development not altogether accounted for by impaired hearing and hospitalization.

Toxic reactions were few. In five cases a generalized maculopapular rash was observed, and in two cases the eosinophil count was 7% and 5%. A peculiar tremor resembling that seen in cerebellar disease was observed in eight patients who received intrathecal streptomycin, but this tremor quickly disappeared. Pleocytosis in the cerebrospinal fluid was relatively common and reached 500 per c.mm. in one case. Renal complications were observed in three cases—frank blood in one case, casts and red blood cells in two cases—but there was no permanent renal damage.

Prognosis depended on: (a) Early diagnosis: choroidal tubercles might lead to early recognition of miliary dissemination. In two of the cases tuberculous meningitis developed while the patients were under treatment with streptomycin for tuberculous bronchopneumonia and miliary tuberculosis, and these cases were diagnosed as a result of routine cerebrospinal fluid examinations. No abnormal clinical signs were observed at the time. (b) Age: the prognosis was worse in children under the age of 3. (c) Cerebrospinal fluid changes: the presence of tubercle bacilli on more than two occasions after starting streptomycin therapy was a bad prognostic sign. (d) Hydrocephalus, as evidenced by skull changes and generalized muscle-wasting, carried a poor prognosis. Radiologically the miliary tubercles might disappear during treatment, although in these cases they were still visible in large numbers at necropsy.

Four cases of influenza meningitis had been treated with intramuscular and intrathecal streptomycin. Injections were continued for from seven to ten days, the cerebrospinal fluid becoming sterile on the second or third day. Three made an uninterrupted recovery, but the fourth case developed spasticity of the left arm two weeks after discharge from hospital and subsequently died from pneumococcal meningitis.

Laboratory Control

Dr. A. C. T. VAUGHAN emphasized the necessity, in view of the ease with which resistance developed, of maintaining strict laboratory control of streptomycin treatment. With one exception, confirmed at necropsy, the tubercle bacillus had been isolated from each patient under treatment at Alder Hey Children's Hospital. An unexpected finding had been the inability to detect any increase in the resistance of the infecting organism isolated post-mortem in those who failed to respond, even when in one case treatment had lasted for sixty-six days.

Dr. C. A. ST. HILL said that streptomycin was an efficient bacteriostatic agent against the tubercle bacillus *in vitro*, but its results in the treatment of tuberculous meningitis were disappointing in many cases. These disappointments were due to a large extent to the formation of adhesions around the brain and spinal cord with consequent hydrocephalus. These adhesions might further hamper the action of the drug by burying the tubercle bacilli and thus protecting them from its influence. It would seem, therefore, that an advance in treatment might follow if some means could be found to prevent the formation of adhesions. There were a number of drugs which might be

used for this purpose, and two patients were being given heparin and streptomycin, but the effect of this treatment could not as yet be ascertained.

Dr. V. COTTON CORNWALL said he felt that the results were bound to be disappointing in a large number of cases of tuberculous meningitis. Dr. Hughes' division of meningitis into at least two groups was important, for it was in the cases associated with milary tuberculosis that the best results had been obtained. The American literature suggested that streptomycin was often useful in recent exudative pulmonary tuberculosis, and he hoped supplies would be available soon for a trial in such cases.

At the same meeting Dr. C. ASTLEY CLARKE read a short paper on asthma.

CREDÉ'S METHOD

A meeting of the North of England Obstetrical and Gynaecological Society was held in Manchester on March 5 with the president, Mr. J. E. STACEY, in the chair.

SIR WILLIAM FLETCHER SHAW said that as a result of recent experiences in the conduct of higher examinations he had come to the opinion that ideas on what constituted Credé's method had changed. In the past he himself had taught, as he had been taught, that it was a method of applying gentle rhythmical stimulation to a sluggish uterus in the third stage to induce it to contract and so separate the placenta; only when it was contracting vigorously was it to be squeezed a little harder and the placenta delivered from the vagina by pushing the uterus gently downwards in the axis of the pelvis. Nowadays there appeared to be a widespread belief that Credé's procedure consisted essentially in extremely forceful squeezing of the uterus to promote separation of the placenta, and he therefore wished to draw attention to Credé's original description of his method (*Klinische Vorträge über Geburtshilfe*, 1853, 1, 600):

"... Failing natural discharge of the placenta... In numerous cases, without exception, successful expulsion of the placenta has been obtained within a quarter or half an hour after the birth of the child, by massage through the abdominal wall around the fundus and body of the uterus—gentle at first and gradually increasing in force, thus producing an artificially stimulated powerful contraction. When this is at its height I grasped the uterus so that I lay in the palm of the hand and the fingers and thumb along the sides of the organ, exerting a gentle and outward pressure. In each case I felt the placenta slide out of the uterus from under my fingers with such an impetus that it was carried through to the very external genitals; or at least to the lowest parts of the vagina."

Sir William Fletcher Shaw concluded from this that Credé meant gentle massage to be used for the purpose only of inducing strong contraction of the uterine muscle, the final squeeze being intended only to push the placenta from the lower uterine segment and the vagina. If vigorous and forceful squeezing of the placenta from the fundus of the uterus was ever justified, it ought not to be associated with Credé's name. Moreover, even the method described by Credé was not original, and had been discussed by John Harvie, who in 1767 wrote:

"... As soon as the child is committed to the care of the nurse let the accoucheur apply his hand upon the belly of the woman, which is then very loose, and he will readily feel the contracting uterus; then, having placed the flat of the hand over it, let him by a light and gentle pressure bring it downwards or towards the pubis, and he will feel the uterus sensibly contracting and then feel it so reduced in size as to be certain the placenta is expelled. By this method he will seldom have anything to do afterwards but to help it through the os externum; if even so much remains undone..."

As in so many other examples in the history of medicine, the name of the originator was not associated with the disease or its treatment, but rather the name of the person who discovered it afresh at some later date.

In the discussion which followed there was general agreement that there should be no interference during the third stage of labour unless there was a clear indication for it, and that energetic squeezing and manipulation of the uterus was dangerous in that it was conducive to placental retention and shock. Many speakers said, too, that the present-day tendency

was to distinguish between squeezing the fundus to promote placental separation (rightly or wrongly attributed to Credé) and expression of the already separated placenta from the lower uterine segment and vagina.

Unusual Cases

Dr. R. M. CORBET (Preston) described a case of pregnancy complicated by a large hydronephrosis.

Mr. JOHN HAMILTON (Liverpool) discussed a case in which he had successfully removed a large fibroid uterus weighing 32 lb (14.5 kg.) from a grossly anaemic woman, and also a case of pregnancy in a bicornate uterus in which the pregnant horn had ruptured spontaneously at the eighteenth week. After removal of the ruptured horn, and of the pregnancy sac from the peritoneal cavity, the patient made a good recovery.

Miss K. LIEBERT (Manchester) described a case of post-abortion general peritonitis treated with streptomycin. A persistent and virulent peritoneal infection did not respond to sulphamezathine, penicillin, or drainage of the abdomen, but was dramatically cured by streptomycin. The organisms concerned were coliform bacilli and non-haemolytic streptococci, both shown to be resistant to penicillin but sensitive to streptomycin.

POST-PARTUM HAEMORRHAGE

At a meeting of the Edinburgh Obstetrical Society on March 11 with the president, Dr. W. F. T. HAULTAIN, in the chair, a paper was presented by Dr. RICHARD DE SOLDENHOFF on haemorrhage in obstetrics.

Dr. de Soldenhoff said that 99 maternal deaths from haemorrhage had been reported to the Department of Health for Scotland in 1946-7; 67 were due to post-partum haemorrhage and some 40% of these were young primiparae. The majority of these women died in hospital, in Dr. de Soldenhoff's opinion because they had been moved to hospital following the birth of the child while suffering from post-haemorrhagic collapse.

He referred to the arrangements in the County of Ayr, where since 1937 a whole-time obstetrician had been employed by the local authority. Since that date this officer had operated an emergency domiciliary service chiefly for the resuscitation of such cases. Dr. de Soldenhoff had held this post since the autumn of 1946. The equipment used was readily transportable and included all the apparatus necessary for transfusion and for dealing with retained placenta, incomplete abortion, etc. It included blood and plasma, and the resuscitation team always carried a citrate-containing flask for the immediate replacement of a portion of the blood donation by the contribution of a relative of the patient taken at the time of transfusion. A supply of high-titre anti-CD serum was included to avoid the dangers of rhesus incompatibility.

Dr. de Soldenhoff then discussed the principles of the management of third-stage haemorrhage, post-partum haemorrhage, antepartum haemorrhage, and incomplete abortion. Immediate manual removal of the placenta was advocated for antepartum haemorrhage of severe degree. He condemned Credé's manoeuvre and advocated the vaginal pack for certain emergency cases of antepartum haemorrhage, and early curettage for incomplete abortion. He warned against the dangers of over-transfusion and advised against slavish reliance upon sphygmomanometer readings as an index of progress.

The paper was discussed by a large number of those present, including the president. It was agreed that the general use of such emergency services as those described was desirable.

Prof. Andre Dreyfus, Professor of General Biology and Dean of the Faculty of Philosophy, Science, and Letters in Sao Paulo University, is in Britain until April 23 under the auspices of the British Council. President of the Brazil-U.S.A. Cultural Union, he is also a member of the boards of cultural societies for relations with Russia, Canada, and Italy. As a geneticist working on *Drosophila*, the purpose of his visit is to meet British geneticists. The Glasgow Royal Technical College have arranged a programme for him in Scotland. He will visit Leeds on April 18-20, and Manchester on April 20-22.

Correspondence

The Four Points

SIR.—We have reached the stage in our fight with the Government when we must have clear-cut convictions, not woolly-minded conceptions masquerading as basic ideals. The issue has become so confused that the average doctor does not know where he stands—e.g., no alternative plan exists, the N.H.S. scheme is unacceptable, the present private service is out of bounds since the B.M.A. is committed to a national service, so all that is left is the N.H.S. with the four amendments (good-will, full capitation, etc.). The question then before us is, Are these four pillars of wisdom—or should I say freedom—well and truly founded, and are they worth fighting for?

Let us examine these four pillars. What do we mean by buying and selling practices? I think most doctors mean continuing the custom exactly as it operates at present. Now, this is impossible, as it involves administrative freedom with the right to appoint one's successor, etc. Indeed, it is comparable to saying that we are willing to work a Government service if we are allowed to run it privately. It is of course an untenable position, and yet I agree it is the only basis on which buying and selling could be justified.

The "master pillar" is that concerning abolition of the basic salary. It is argued that if we are paid by capitation only we are being protected from a full-time salaried service—a very laudable objective. It is true reference would have to be made to Parliament before such a step could be taken, but note all we have gained is the protection of a Government pledged to a full-time salaried service—truly a Pyrrhic victory.

The third pillar, concerning direction, is I think very weak. Obviously the main idea is to protect doctors' being forced into undesirable areas. Actually I feel greater difficulty will be experienced in getting medical men to carry out the proposed scheme in places such as Southport, Harrogate, etc., where we are dealing with an aged and ailing population, and where 1,000 patients would probably be a full-time job. Some adjustable scheme as that envisaged in the basic salary might prove very useful.

As regards the fourth pillar—viz., right of appeal to the courts—there is undoubtedly a case that could be argued cogently, but are the terms offered doctors different from those operating in other Government departments, and has the experience gained in these other departments been such as to create uneasiness? I do not think so.

To sum up, could these four amendments be elevated to the standard of convictions strong enough to sustain a fight? If my reasoning be accepted they certainly could not, as they are mainly myths. It must not be imagined that I am anxious for a Government service; I am only anxious to clarify the rodomontade that so many doctors are indulging in under the guise of saving the profession and the public. If we agree to a national medical service at all then we must, I think, under existing Government regulations yield administrative freedom, but we should make very sure that professional freedom is established. As regards a full-time salaried service, the only protection I know of is the will of the profession to resist it no matter what Government is in control. Even a clause in the Act could be altered.

I think it is unfortunate that the issues dealt with above should have excluded so completely all light on the business side of the proposed service.—I am, etc.,

Southport

S. H. STEWART.

Choosing Successor

SIR.—I suggest that a simple way of meeting our objections to forfeiting our freedom by the ban on the sale of practices would be to allow practitioners an unfettered right to choose their successors. Our main objection to the ban is the interference with our freedom to practise where we will. If the Local Medical Committee and the Medical Practice Committees were abandoned and the above method adopted, there would be no legitimate objection to the State purchasing our practices instead of by private arrangement.—I am, etc.,

Boston Cambs

A. E. MOORE.

Can Consultant Practice Survive?

SIR.—The consultants have been preoccupied in defending the interests of the general practitioner. Only here and there is a lone voice raised to inquire as to their future. No contracts have appeared for signature, and they are being lured into inactivity awaiting the decision of the Spens Committee. Could the Minister of Health be more pleased by any situation?

What are his aims? The consultant is in short supply. Private practice is anathema to the Labour Party. The consultant's service must be rationed and equally distributed in the Socialist ideal world. The poor must not feel that his more prosperous brother can avail himself of a better service. Under the new scheme, when specialist services are available without extra payment to one and all, can it be imagined that consulting practice as it now exists can survive? Here and there it may do. The large bulk of consultants will have to augment their private earnings—and will considerably come to rely on this source—from payment for their hospital services. If we need any indication of the scale, the L.C.C. payment of £700 a year for practically a half-time appointment may serve as a guide of a specialist's salary.

When the scheme has been in operation for a time, private consulting practice will dwindle further, and those holding such appointments will feel compelled to seek fuller employment under the authority. These duties are hardly recreational. The output expected is far from modest. Hospital appointments will probably be paid at a similar rate, and it can be easily envisaged that—in the absence of private practice—consultants with even two or three hospital appointments could not make a living in the larger centres. Herein lies the subtle process of *negative direction*—a form of economic compulsion driving the specialist out of his practice to eke out an existence in uncongenial surroundings, a servant of the new machine, painfully aware of its economic strength. That this is not imaginative, something that is now occurring will indicate.

I have knowledge of a hospital where the consultants have been required by regulations to attend for a certain number of sessions per week, so that their duties should be adequately accomplished. This hospital staff made application to the Ministry for payment—without prejudice to the future—on this sessional basis which they had voluntarily observed in the past. The Ministry have indicated that the attendances were far too numerous.

Billion dollar loans and the Marshall Plan may permit for a while longer this inflationary recklessness that beguiles the consultant into believing that payment under the new scheme is in the nature of a purloin. But the days of reckoning are numbered. Financial stringency, "mass-produced" specializing, and a tightened exchequer will make him realize that he should have thought, and thought hard, while he still had a chance to devise a way of escape.

It appears immodest to consider the financial side of the State scheme, but when it is being used as a weapon to exploit a class of professional men it calls for ventilation. We must retain: (1) freedom, and (2) security of tenure. This can only happen if we plan in unison not to expose ourselves to the possibility of economic strangulation. The general practitioner knows what he wants. It is time the consultant's demands for self-protection were formulated. The hospitals become State-owned in July. Is forgoing our salary our most vigorous protest against State servitude?—I am, etc.,

London, W.I.

JOHN SOPHIAN.

Hoyland Doctors Unite

SIR.—We the undersigned, all general practitioners in adjoining districts and all having voted "No" in the recent plebiscite, have formed ourselves into a committee for the purposes of (1) mutual protection and moral support; (2) the dissemination of facts to the public as opposed to rumour and misrepresentation.

We are holding public meetings in the districts in which we practise, and able medical speakers are being invited to explain the reasons for the doctors' objections to the National Health Acts of 1946 and 1947 and to discuss the patients' angle on the National Health Service. These meetings will be non-political and, as far as possible non-controversial. The audiences will

be encouraged to ask questions and the local doctors will be supported by those from the other districts concerned.

At our first committee meeting the following resolutions were passed, and submitted to those who had been unable to attend:

(1) For the next three months no transfer of National Health Insurance patients excepting those coming on to the panel for the first time or from outside districts. This resolution was passed for mutual protection against the suggestion made in some quarters that N.H.I. patients should threaten to withdraw their medical cards unless their doctor agreed to enter the National Health Service.

(2) The British Medical Association to be asked to take immediate action and not wait until July 5.

(3) No medical cards issued under the National Health Service Acts, 1946 and 1947, to be accepted by any doctor in the districts concerned.

(4) Public meetings to be held in all districts after March 17 to put the doctors' case before the patients.

We feel that if practitioners in each district or group of districts who are opposed to the Acts in their present form would join together in this way the unity of the profession would be greatly strengthened. Special attention should be given to those who may be wavering because of financial worries. It should be a case of "all for one and one for all," each practitioner helping and supporting his neighbour in every way possible.

Let us learn to have faith in ourselves and in each other, for only by presenting a united front can we hope to win the battle for professional freedom. Let all who value the ideals and traditions of medicine and who refuse to betray the medical men and women of the future join together throughout the country and cry "Halt" to the forces of totalitarianism. We shall fight and fight hard in our own area. Shall we fight alone?—We are, etc.,

Must the Doctor Tell?

SIR,—Although my Service numbers have only just had time to dry (8 months) I myself have had enough of direction and regulation. There is, however, one regulation that worries me now and may worry patients after July 5. I am instructed to inform my commanding officer of all second infections with venereal disease in other ranks and all first infections in the case of officers. This makes nonsense of the "confidential" advertisements one sees in civilian life, and incidentally of the Hippocratic ideal. If I refuse I am disobeying an order. If I comply I am the less a doctor. If some "sea lawyer" takes me to court for a breach of faith, am I or is the R.A.F. held responsible?

So much for my own difficulty, which has arisen through being a nationalized doctor in a nationalized force. The miner is nationalized; after July 5 the doctor is nationalized. The arguments applied to the airmen and myself will apply to doctor and miner. "The V.D. rate is high in the industry. The problem must be beaten." The doctor must inform the mine manager the miner has V.D. The logical sequence to this is to carry out "F.F.I." inspections in the nationalized industries, for if confidence is no longer to be maintained the patients will attempt to hide their condition.

I would be grateful if the eminent members of my profession would give an ethical ruling on the confidential issue and if Mr. Bevan would give his ruling on the same issue in its application to industry. It may lose him votes but it would at least be honest.

Finally, may I sympathize with the doctors' wives? My record number of signatures for one afternoon so far is 52. The clerks had to spend a long time preparing the forms for signature. The doctor's wife will now have to prepare them, for they will surely be necessary.—I am, etc.,

SERVING OFFICER.

A State Service

SIR,—I have just received my *Journal* for Feb. 7, containing an account of the consultants' meeting held on Jan. 27. I was amused by and read with some cynicism Dr. H. B. Morgan's statement that a number of services, such as the Public Health Service and Colonial Medical Service were full-time and functioning satisfactorily. I can only speak of the latter and use it as a pointer of things to come under Mr. Bevan's scheme.

Does functioning satisfactorily include one director, deputy directors, seven assistant directors, ten administrative senior officers to control 13 specialists and 109 general medical officers? Yet that is the fact stated in the latest staff list of the large colony. All 22 administrators are qualified doctors. Initiative, enterprise, ability, and skill are of far less value than a "good book." No one wants that for the United Kingdom—not even the present Minister of Health, probably. It is a fact, however, that once the administrative germ takes hold of the body medical petty bureaucracy engenders frustration, marked among the keen clinicians, of whom there are not a few. Meanwhile clerks, both medical and lay, flourish.

Only one out of the 14 doctors from the United Kingdom working in this area would have voted for the Health Service in the recent plebiscite had they received papers in time, I understand.

For my crime of being a Civil Servant I am not allowed to sign my name to this letter under the direst of penalties. The same could easily occur at home in a full State service—I am, etc.,

F.R.C.S., COLONIAL SERVICE.

Rural Remuneration

SIR,—As has already been noted, the proposed N.H.S. remuneration, although it may be adequate in industrial areas will cause great hardship or worse to many rural practitioners. The industrial practice is closely grouped around the main surgery, to which patients have ready access by public transport. Such visiting as there is is from door to door. In the country not only can the blind, the halt, the aged, and the infants not come to the surgery owing to hills, distance, lack of transport or stress of weather, but when a visit to them is made arrival at the gate may mean a further climb of 50 or 100 feet of long steep path. A recent census over two months showed a ratio of 4.1 visits to every surgery attendance.

My partner and I live four miles apart and serve some 25 square miles of broken country. One of us has patients on and across a rapid tidal estuary. In the winter there is no ferry, which means getting out one's own boat and rowing. During the last six months 33 such visits were made. On two days gales made anything but visual communication impossible. On a time-energy basis each such visit equals six or more ordinary ones. As this harbour work is within a mile's radius of the surgery no mileage is claimable under N.H.I. Moreover, mileage allowance as at present calculated is a farce. On a group of patients in a hamlet two miles away on a main road it may be reasonable, but the more inaccessible patients never present their cards until ill. Mileage should be paid on an item-of-service basis, as is now quite satisfactorily done by the Admiralty, Army, and other departments.

The total population in this area is probably under 3,000 and it seems impossible on the terms offered that we shall not be down several hundred pounds on our present income. It should be borne in mind too that we are "at risk" for the whole population of the area, not as in a city with the risk spread over many practitioners. That work will be greatly increased under N.H.S. is generally admitted—for example, extra visits solely for the purposes of certification (e.g., mild infectious diseases which must not come to the surgery and would normally be seen once or not at all). Further, whereas N.H.I. deals with patients healthy enough to be at work, N.H.S. will include a big percentage of primarily sick and chronic cases who must be visited.

Personally I think that the remuneration so far offered, however it is distributed, will be quite inadequate for good work, though possibly enough for mass-produced certification in a city. Unfortunately the legislators of all parties when making

ulations think always of straight streets of numbered houses, whether it be health, housing, rations, traffic, or whatever. Any of the difficulties resulting from the application of these regulations to country conditions would be laughable if they were not so wasteful and exasperating.—I am, etc.,

Jewson Fatters, S. Devon.

W. F. BENSTED-SMITH.

Plea for Compromise

SIR,—I am and always have been a convinced opponent of comprehensive national health service. Here the operative word is "comprehensive," as Government service can be perfectly satisfying. I have spent nearly 30 years in it and should now what I am talking about. But what made such service satisfying is the fact that nearly 95% of the profession were inside it. If an individual felt himself aggrieved by the conditions of his service, he could always retire and go into civil practice. If the grievance was a general one, the B.M.A. could, and did on occasion with great effect, turn off the supply at source. Once the service becomes comprehensive both these safeguards vanish. For the dissatisfied individual there is no remedy but to emigrate, as a certain Member cynically remarked in the House; for the generality there is no refuge.

It is therefore with real apprehension that I see looming before us the prospect of such a comprehensive service. It is possible that resistance at an earlier stage might have avoided it. The Beveridge Report contained in germ all the most objectionable features of the present Act. A firm stand then might have reduced the whole scheme to its proper proportions: an extension of the N.H.I. Act. A very grave error was made when, instead of submitting an alternative scheme of our own, we agreed to negotiate on the Government proposals only, by so doing we admitted the principle of direct Ministerial control. The acceptance of the 100% principle practically made the State our sole paymaster and deprived us of the strength independent income would have given us.

But it is no use crying over spilt milk; we must now face the grim prospect of a Government-controlled service which we have accepted in toto except for some of the details as to how that control is to be exercised. And this is surely the time for some give and take on both sides. The right of appeal to the courts the Minister may well yield us. It will rarely be exercised. We on our side might yield on the question of the ownership of our practices. It is, I think, an illusion at this will render us more helpless. The power of the State which we have yielded is so strong that it can make the difference.

The remaining two points are matters in which concessions could be made on both sides. The right to refuse permission to settle in an over-doctored district is harmless; it prevents over-crowding. The right to direct men into unpopular districts is objectionable. Men should be coaxed, not driven into such districts. By "coaxed" I mean such inducements as higher honours and the right to a move after a certain number of years. The danger about a universal basic salary is that it easily leads to a salaried service. This danger would disappear if we restricted to men setting up independent practice for the first time and allowed gradually to disappear. Here I should like to adopt a suggestion made to me that the initial salary could be at least double the present figure and taper off in succeeding years until it vanished altogether in, say, five years. This would give the maximum help when it was most needed and act as an incentive to work. I make no claim that my suggestions are a solution of our difficulties, but I do make a plea that that genius for compromise for which this country is rightly famed may be allowed to prevail before further bitterness.—I am, etc.,

Andover, Hants

Morality of the State

SIR,—Dr. Stephen Taylor, though he had outlined his views quite clearly (March 6, p. 463), does not yet seem to understand why we are disturbed. Yet out of his own mouth we have the answer. Under item 4 of his letter he states that an amending Act would give us no protection whatever. In other words, no guarantee by those who represent the State is worth much.

Surely, Sir, this is the crux of the issue. The historian knows that history teems with broken pledges; these are broken as freely, probably more so, by the State than by individuals. In fact the individual, even if he would, is often bound to his promise by laws imposed by the State. Socialists cannot have it both ways. They cannot elevate the State above the individual, permit it to break all the rules of manners and ethics, and then expect us to give it trust, loyalty, and respect.

This issue, so often evaded by those charged with the defence of morality, is of fundamental importance at a time when worse tyrannies than Socialism are just over the water. I do not think many of us could feel happy under the Act until some more definite safeguards against abuse of power by the State are forthcoming. It may not be possible to bind any future government to anything, but we should be well aware that tyranny may be practised by the so-called democracies as much as by Fascists, Communists, and absolute monarchs.

If we accept that the State should be as moral in its actions as the individual, how does Dr. Taylor regard the threat to which general practitioners are now exposed? The Minister says in effect, "Come into the Service or lose your money. I will not buy your practice and you may not sell to another." Is this morally defensible? Will Dr. Taylor tell us in these columns if it is?

The Act, as it stands, is misleading to the public, since many of the things published in the prospectus are not there, nor can they be for years to come. Can Dr. Taylor wonder then that we feel great moral indignation, not only because of the injustice with which we are threatened but because of the fraud at which we are asked to connive? If Dr. Taylor detests intimidation and coercion, as do all those with a sense of fair play, I suggest that he considers these points. He might also like to make clear to the Surrey Federation of Trades Councils that their proposed questionnaire to doctors is unethical and contrary to the spirit of true Socialism.—I am, etc.,

Hadley Wood, Herts.

Refinancing the Service

SIR,—My letter "Financing the Service" (Feb. 14, p. 311) has been justified rather sooner than I expected by the revised estimates of the cost of the N.H.S. which have now been issued, and the miscalculations can be seen to be even more gross than I anticipated.

The sum of £87 million for hospital and specialist service has now been raised to £134 million, exposing an original error of 54%. The sum of £45 million for the G.P., optical, pharmaceutical, and dental service has been stepped up to £60 million, an error of 33%.

Such casual manipulation of "meaningless symbols" by the back-room boys of Whitehall cannot be condoned. Or were the underestimates deliberately designed to facilitate the passage of the Bill through Parliament? Let us hope, as taxpayers if not as doctors, that the watchdogs of the Treasury will be among the first to claim dental benefit and be fitted with new acrylic-resin, or preferably stainless-steel, teeth.—I am, etc.,

Bournemouth.

Methods of Fighting

SIR,—I am a realist, and as I sat at the Representative Meeting on March 17 I felt it was unfortunate that there were not more in the medical profession, and particularly so on the Council. Most of us agree that this comprehensive service is non-political and was introduced by a coalition government for purposes of certification essential for the successful running of the social insurance scheme rather than for a crying need for improved treatment of the sick.

A motion was proposed that doctors should attend the sick after July 5, but no certificates other than for infectious diseases, lunacy, and death should be issued. Dr. Guy Dain, Chairman of Council, said he was amazed that such a motion should be brought forward, and he was supported by Dr. Gregg that to withhold certificates was a paltry act. The motion was rejected by your representatives.

As a realist, I am amazed that the Council should ask the members of the B.M.A. for the far from paltry sum of £100 as a first contribution for a fight for which they have obviously

no stomach. An earlier speaker pointed out that, if you are to have a fight, someone must get hurt. In our fight the Council are determined that it shall not be the patient; we can rely on Mr. Bevan to look after himself; and so I will give you one guess who will get hurt. When the Council announce on what lines they intend to fight I shall decide whether to subscribe or not, but if they continue their present methods they will certainly lose the fight and our money.—I am, etc.,

Camberley.

LESLIE HARTLEY.

The Alternative

SIR,—The *Journal* (Supplement, March 27, p. 56) reports Dr. E. A. Gregg, whose position lends authority to his voice, as saying, "Our alternative is the National Health Service scheme with the changes in it for which we have asked and of which you are all aware." If this statement represents the full content of our opposition to his scheme Mr. Bevan may well sit back content in the belief that he will soon see a landslide in his favour just as did another very adroit, very intelligent Welsh politician who manœuvred the profession into an untenable position a generation ago. It must be obvious to anyone who has followed your correspondence columns that many who voted against the Service did so from motives which had little connexion with the four so-called principles. I venture to suggest that a great number would feel chagrined and frustrated if Mr. Bevan were to yield on all four points and thus leave us with no option but to agree to serve his ends.

I cannot believe that I am alone in opposing the scheme because it appears to be a gigantic fraud, a vast confidence trick about to be perpetrated on the British public. We know that those who issue fraudulent company prospectuses are in danger of finding themselves behind prison walls, in company with practitioners of the confidence trick, but at least their victims have a chance to say "No" to such gentry; whereas everyone will be legally obliged to pay for a service which Mr. Bevan knows full well must fall far short of his promises for many years, even if he has the enthusiastic co-operation of the profession from the outset. But the Minister goes farther than Dr. Gregg and announces, through his mouthpiece Dr. Stephen Piggott, that even with one-third of the necessary staff he intends to run his service on the appointed day.

Dr. Gregg seems either to hold an entirely different view as to the value of the Service under existing circumstances or to believe that this aspect is of no concern to us. If he can tell me of any real value to the community which the Service will possess I shall be very grateful to him, but if he cannot he is in effect declaring that, if we retain the right to sell our practices, are not forced to accept salaries, are free to practise where we will, and may appeal to the courts if illegally dismissed, then we will be the willing accomplices and accessories of this gigantic immorality. If the suggested interpretation of Dr. Gregg's statement is fair and accurate there seems to be no very obvious reason for surprise that Press, public, and Parliament are predominantly hostile, or at least distrustful, not of the Minister but of us.—I am, etc.,

Launceston, Cornwall.

DONALD M. O'CONNOR.

The Doctor-Patient Relationship

SIR,—The fight for freedom by our colleagues at home is being watched with keen interest out here, but it is a matter of some comment that no stress has been laid on what is after all the crux of the situation—namely, the destruction by the Act of the doctor-patient relationship. I take the titles of letters on p. 311 of your issue of Feb. 14: Alternative to Salary, Financing the Service, Compensation, Remuneration in the N.H.S., Goodwill in Practices—all dealing with the material aspect of our fight, and a side of it in which the general public—whose good will we deserve and must have—is either not interested, or which it is apt to misconstrue.

We, however, know from the experience of medicine in existing services that one of the first things a doctor tends to lose is that sympathy, understanding of the individual patient, and knowledge of and interest in his environment which taken together make up the doctor-patient relationship and which result in the patient that confidence which is so often three-quarters of the battle.
